 No solution found, search does not terminate because of cycles!

CSE 3402 Winter 2010 Yves Lapierre & Fabien Baerhuus

4

Selection Rule.

- The example shows that order states are selected from the frontier has a critical effect on the operation of the search.
 - Whether or not a solution is found
 - The cost of the solution found.
 - The time and space required by the search.

CSE 3402 Winter 2010 Yves Laperrance & Fabrice Bacchus

5

Critical Properties of Search.

- **Completeness:** will the search always find a solution if a solution exists?
- **Optimality:** will the search always find the least cost solution? (when actions have costs)
- **Time complexity:** what is the maximum number of nodes that can be expanded or generated?
- **Space complexity:** what is the maximum number of nodes that have to be stored in memory?

CSE 3402 Winter 2010 Yves Laperrance & Fabrice Bacchus

6

Uninformed Search Strategies

- These are strategies that adopt a fixed rule for selecting the next state to be expanded.
- The rule is always the same whatever the search problem being solved.
- These strategies do not take into account any domain specific information about the particular search problem.
- Popular uninformed search techniques:
 - Breadth-First, Uniform-Cost, Depth-First, Depth-Limited, and Iterative-Deepening search.

CSE 3402 Winter 2010 Yves Laperrance & Fabrice Bacchus

7

Selecting vs. Sorting

- A simple equivalence we will exploit
 - Order the elements on the frontier.
 - Always select the first element.
- Any selection rule can be achieved by employing an appropriate ordering of the frontier set.

CSE 3402 Winter 2010 Yves Laperrance & Fabrice Bacchus

8

Breadth First.

- Place the successors of the current state at the end of the frontier.
- Example:
 - let the states be the positive integers $\{0, 1, 2, \dots\}$
 - let each state n have as successors $n+1$ and $n+2$
 - E.g. $S(1) = \{2, 3\}$; $S(10) = \{11, 12\}$
 - Start state 0
 - Goal state 5

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

9

Breadth First Example.

```
{0}
{1,2}
{2,2,3}
{2,3,3,4}
{3,3,4,3,4}
{3,4,3,4,4,5}
...
```

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

10

Breadth First Properties

- Measuring time and space complexity.
 - let b be the maximum number of successors of any state.
 - let d be the number of actions in the shortest solution.

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

11

Breadth First Properties

- Completeness?
 - The length of the path from the initial state to the expanded state must increase monotonically.
 - we replace each expanded state with states on longer paths.
 - All shorter paths are expanded prior before any longer path.
 - Hence, eventually we must examine all paths of length d , and thus find the shortest solution.

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

12

Breadth First Properties

- Time Complexity?

- $1 + b + b^2 + b^3 + \dots + b^{d-1} + b^d + b(b^d - 1) = O(b^{d+1})$

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Baerthou

13

Breadth First Properties

- Space Complexity?

- $O(b^{d+1})$: If goal node is last node at level d , all of the successors of the other nodes will be on the frontier when the goal node is expanded $b(b^d - 1)$

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Baerthou

14

Breadth First Properties

- Optimality?

- Will find shortest length solution
 - least cost solution?

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Baerthou

15

Breadth First Properties

- Space complexity is a real problem.

- E.g., let $b = 10$, and say 1000 nodes can be expanded per second and each node requires 100 bytes of storage:

Depth	Nodes	Time	Memory
1	1	1 millisecc.	100 bytes
6	10^6	18 mins.	111 MB
8	10^8	31 hrs.	11 GB

- Run out of space long before we run out of time in most applications.

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Baerthou

16

Uniform Cost Search.

- Keep the frontier sorted in increasing cost of the path to a node.
- Always expand the least cost node.
- Identical to Breadth First if each transition has the same cost.
- Example:
 - let the states be the positive integers $\{0, 1, 2, \dots\}$
 - let each state n have as successors $n+1$ and $n+2$
 - Say that the $n+1$ action has cost 2, while the $n+2$ action has cost 3.

CSE 3402 Winter 2010 Yves Laparacne & Fabrice Bacchus

17

Uniform Cost Search.

```
{0[0]}
{1 [2], 2[3]}
{2[3], 2[4], 3[5]}
{2[4], 3[5], 3[5], 4[6]}
{3[5], 3[5], 4[6], 3[6], 4[7]}
...
```

CSE 3402 Winter 2010 Yves Laparacne & Fabrice Bacchus

18

Uniform-Cost Search

- Completeness?
 - If each transition has costs $\geq \epsilon > 0$.
 - The previous argument used for breadth first search holds: the cost of the expanded state must increase monotonically.

CSE 3402 Winter 2010 Yves Laparacne & Fabrice Bacchus

19

Uniform-Cost Search

- Time and Space Complexity?
 - $O(b^{C^*/\epsilon})$ where C^* is the cost of the optimal solution.
 - Difficulty is that there may be many long paths with cost $\leq C^*$; Uniform-cost search must explore them all.

CSE 3402 Winter 2010 Yves Laparacne & Fabrice Bacchus

20

Uniform-Cost Search

- **Optimality?**
 - Finds optimal solution if each transition has cost $\geq \epsilon > 0$.
 - Explores paths in the search space in increasing order of cost. So must find minimum cost path to a goal before finding any higher costs paths.

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

21

Uniform-Cost Search. Proof of Optimality.

1. Claim: Let $c(n)$ be the cost of the path to node n . If n_2 is expanded after n_1 then $c(n_1) \leq c(n_2)$.

Proof:

- If n_2 was on the frontier when n_1 was expanded, in which case $c(n_2) \geq c(n_1)$ else n_1 would not have been selected for expansion.
- If n_2 was added to the frontier when n_1 was expanded, in which case $c(n_2) \geq c(n_1)$ since the path to n_2 extends the path to n_1 .
- If n_2 is a successor of a node n_3 that was on the frontier or added when n_1 was expanded, then $c(n_2) > c(n_3)$ and $c(n_3) \geq c(n_1)$ by the above arguments.

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

22

Uniform-Cost Search. Proof of Optimality.

2. Claim: When n is expanded every path with cost strictly less than $c(n)$ has already been expanded (i.e., every node on it has been expanded).

Proof:

- Let $\langle \text{Start}, n_0, n_1, \dots, n_k \rangle$ be a path with cost less than $c(n)$. Let n_i be the last node on this path that has been expanded. $\langle \text{Start}, n_0, n_1, n_{i-1}, n_i, n_{i+1}, \dots, n_k \rangle$.
- n_{i+1} must be on the frontier, also $c(n_{i+1}) < c(n)$ since the cost of the entire path to n_k is $< c(n)$.
- But then uniform-cost would have expanded n_{i+1} not n !
- So every node on this path must already be expanded, i.e. this path has already been expanded. QED

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

23

Uniform-Cost Search. Proof of Optimality.

3. The first time uniform-cost expands a state, it has found the minimal cost path to it (it might later find other paths to the same state).

Proof:

- No cheaper path exists, else that path would have been expanded before.
- No cheaper path will be discovered later, as all those paths must be at least as expensive.
- So, when a goal state is expanded, the path to it must be optimal.

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

24

Depth First Search

- Place the successors of the current state at the front of the frontier.

CSE 3402 Winter 2010 Yves Laparacne & Fabien Bacchus

25

Depth First Search Example

(applied to the example of Breadth First search)

```
{0}
{1,2}
{2,3,2}
{3,4,3,2}
{4,5,4,3,2}
{5,6,5,4,3,2}
...
```

CSE 3402 Winter 2010 Yves Laparacne & Fabien Bacchus

26

Depth First Properties

- Completeness?
 - Infinite paths?
 - Prune paths with duplicate states?
- Optimality?

CSE 3402 Winter 2010 Yves Laparacne & Fabien Bacchus

27

Depth First Properties

- Time Complexity?
 - $O(b^m)$ where m is the length of the longest path in the state space.
 - Very bad if m is much larger than d , but if there are many solution paths it can be much faster than breadth first.

CSE 3402 Winter 2010 Yves Laparacne & Fabien Bacchus

28

Depth First Backtrack Points

- At each step, all nodes in the frontier (except the head) are backtrack points (see example and draw the tree for state-space).

Depth First Properties

- Space Complexity?
 - $O(bm)$, linear space!
 - Only explore a single path at a time.
 - The frontier only contains the deepest states on the current path along with the backtrack points.

Depth Limited Search

- Breadth first has computational, especially, space problems. Depth first can run off down a very long (or infinite) path.
- Depth limited search.
 - Perform depth first search but only to a pre-specified depth limit L .
 - No node on a path that is more than L steps from the initial state is placed on the Frontier.
 - We "truncate" the search by looking only at paths of length L or less.
- Now infinite length paths are not a problem.
- But will only find a solution if a solution of length $\leq L$ exists.

Depth Limited Search

```
DLS(Frontier, Successors, Goal?)
  If Frontier is empty return failure
  Curr = select state from Frontier
  If Goal?(Curr) return Curr.
  If Depth(Curr) < L
    Frontier' = (Frontier - {Curr}) U Successors(Curr)
  Else
    Frontier' = Frontier - {Curr}
    CutOffOccured = TRUE.
  return DLS(Frontier', Successors, Goal?)
```

Iterative Deepening Search.

- Take the idea of depth limited search one step further.
- Starting at depth limit $L = 0$, we iteratively increase the depth limit, performing a depth limited search for each depth limit.
- Stop if no solution is found, or if the depth limited search failed without cutting off any nodes because of the depth limit.

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

33

Iterative Deepening Search Example

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

34

Iterative Deepening Search Properties

- Completeness?
 - Yes, if solution of length d exists, will the search will find it when $L = d$.
- Time Complexity?

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

35

Iterative Deepening Search Properties

- Time Complexity
 - $(d+1)b^0 + db^1 + (d-1)b^2 + \dots + b^d = O(b^d)$
 - E.g. $b=4, d=10$
 - $(11)*4^0 + 10*4^1 + 9*4^2 + \dots + 2*4^9 = 815,555$
 - $4^{10} = 1,048,576$
 - Most nodes lie on bottom layer.
 - In fact IDS can be more efficient than breadth first search: nodes at limit are not expanded. BFS must expand all nodes until it expands a goal node.

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

36

Iterative Deepening Search Properties

- Space Complexity
 - $O(bd)$ Still linear!
- Optimal?
 - Will find shortest length solution which is optimal if costs are uniform.
 - If costs are not uniform, we can use a "cost" bound instead.
 - Only expand paths of cost less than the cost bound.
 - Keep track of the minimum cost unexpanded path in each depth first iteration, increase the cost bound to this on the next iteration.
 - This can be very expensive. Need as many iterations of the search as there are distinct path costs.

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

37

Iterative Deepening Search Properties

- Consider space with three paths of length 3, but each action having a distinct cost.

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

38

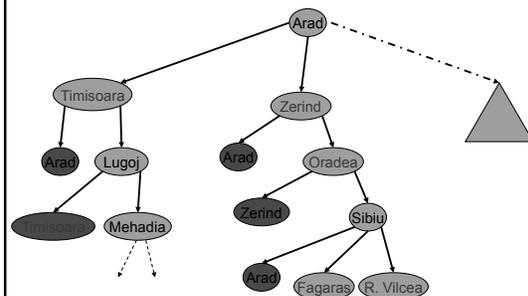

Cycle Checking

- Path checking
 - Paths are stored on the frontier (this allows us to output the solution path).
 - If $\langle S, n_1, \dots, n_k \rangle$ is a path to node n_k , and we expand n_k to obtain child c , we have
 - $\langle S, n_1, \dots, n_k, c \rangle$
 - As the path to "c".
 - Path checking:
 - Ensure that the state c is not equal to the state reached by any ancestor of c along this path.

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

39

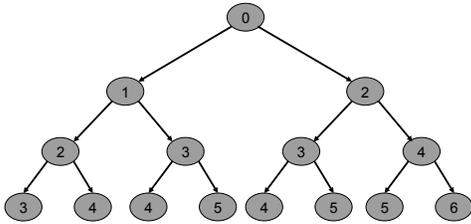

Path Checking Example

CSE 3402 Winter 2010 Yves Lapersonne & Fabrice Bacchus

40

Path Checking Example

CSE 3402 Winter 2010 Yves Laperrance & Fabrice Bacchus

41

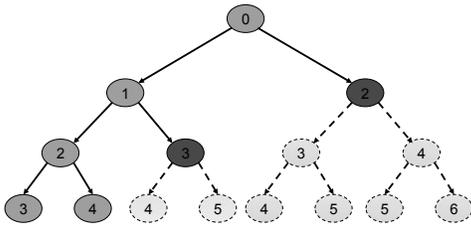

Cycle Checking

- Cycle Checking.
 - Keep track of all states previously expanded during the search.
 - When we expand n_k to obtain child c
 - ensure that c is not equal to any previously expanded state.
 - This is called cycle checking, or multiple path checking.
 - Why can't we utilize this technique with depth-first search?
 - If we use cycle checking in depth-first search what happens to space complexity.

CSE 3402 Winter 2010 Yves Laperrance & Fabrice Bacchus

42

Cycle Checking Example

CSE 3402 Winter 2010 Yves Laperrance & Fabrice Bacchus

43

Cycle Checking

- High space complexity, only useful with breadth first search.
- There is an additional issue when we are looking for an optimal solution
 - With uniform-cost search, we still find an optimal solution
 - The first time uniform-cost expands a state it has found the minimal cost path to it.
 - This means that the nodes rejected by cycle checking can't have better paths.
 - We will see later that we don't always have this property when we do heuristic search.

CSE 3402 Winter 2010 Yves Laperrance & Fabrice Bacchus

44
