Tree-Structured Indexes

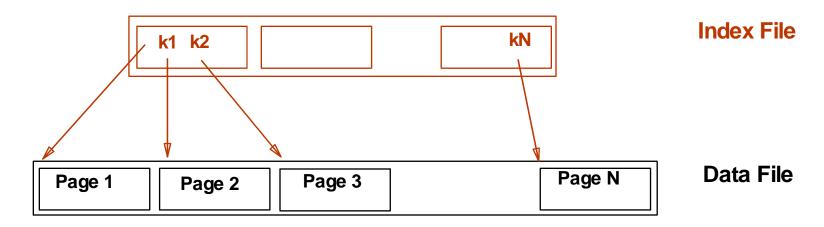

Chapter 10

Introduction

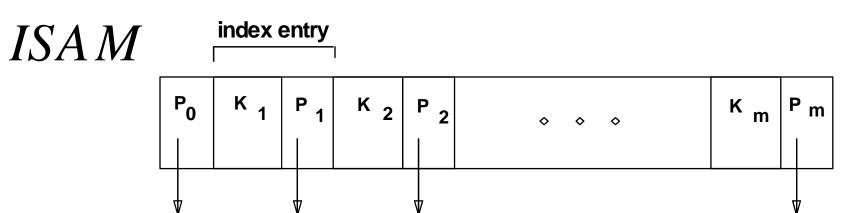

- As for any index, 3 alternatives for data entries k^* :
 - Data record with key value k
 - $\langle \mathbf{k} \rangle$, rid of data record with search key value $\mathbf{k} \rangle$
 - \bullet <**k**, list of rids of data records with search key **k**>
- Choice is orthogonal to the *indexing technique* used to locate data entries k*.
- ❖ Tree-structured indexing techniques support both range searches and equality searches.
- \bigstar <u>ISAM</u>: static structure; $\underline{B + tree}$: dynamic, adjusts gracefully under inserts and deletes.

Range Searches

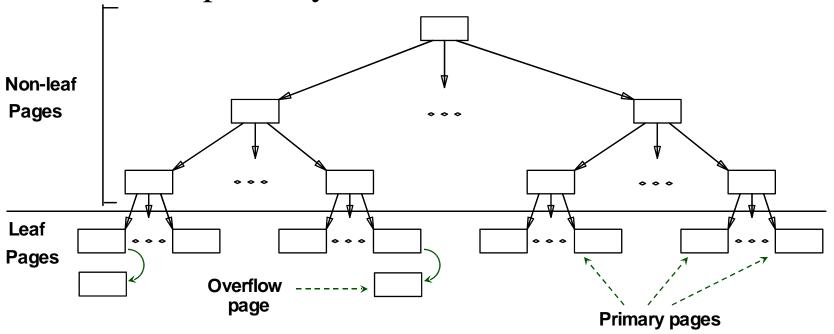

- \Leftrightarrow "Find all students with gpa > 3.0"
 - If data is in sorted file, do binary search to find first such student, then scan to find others.
 - Cost of binary search can be quite high.
- ❖ Simple idea: Create an 'index' file.

❖ Can do binary search on (smaller) index file!

❖ Index file may still be quite large. But we can apply the idea repeatedly!

* Leaf pages contain data entries.

Comments on ISAM

- * File creation: Leaf (data) pages allocated sequentially, sorted by search key; then index pages allocated, then space for overflow pages.
- ❖ *Index entries*: <search key value, page id>; they 'direct' search for *data entries*, which are in leaf pages.
- * <u>Search</u>: Start at root; use key comparisons to go to leaf. Cost is $\log_{F} N$; F = # entries/index pg, N = # leaf pgs
- *Insert*: Find leaf data entry belongs to, and put it there.
- <u>Delete</u>: Find and remove from leaf; if empty overflow page, de-allocate.
 - **Static tree structure**: *inserts/deletes affect only leaf pages*.

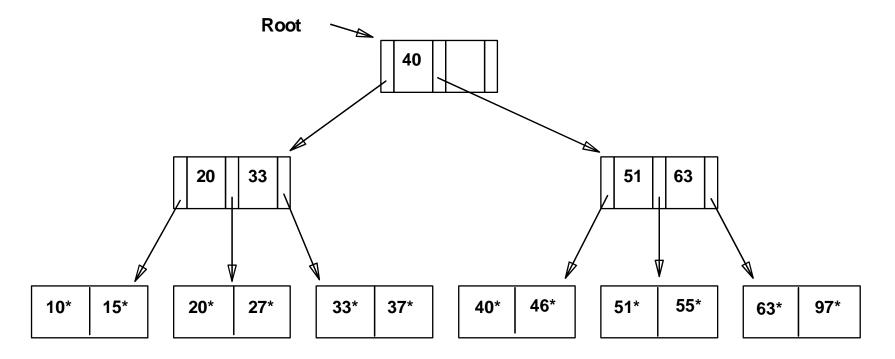

Data Pages

Index Pages

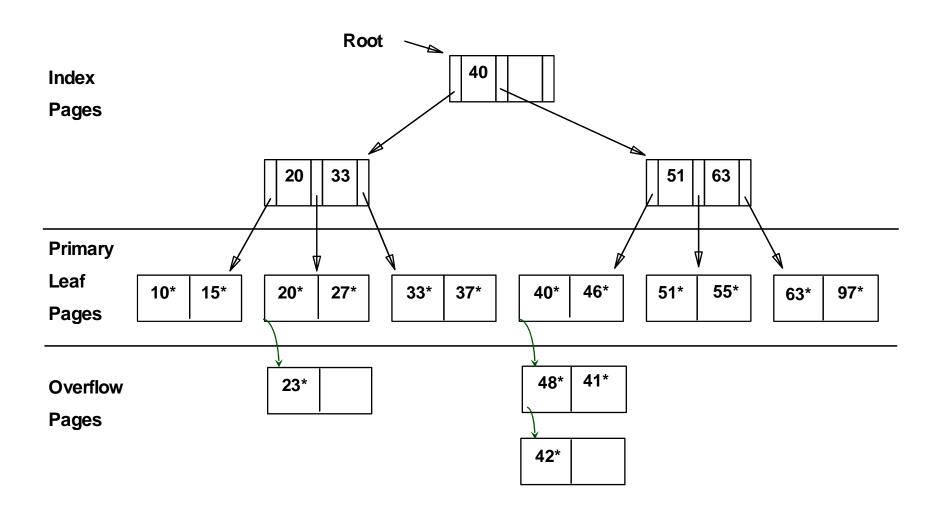

Overflow pages

Example ISAM Tree

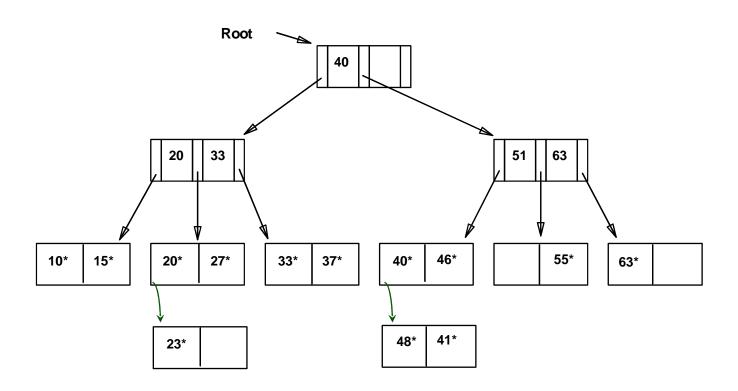

❖ Each node can hold 2 entries; no need for `next-leaf-page' pointers. (Why?)

After Inserting 23*, 48*, 41*, 42* ...

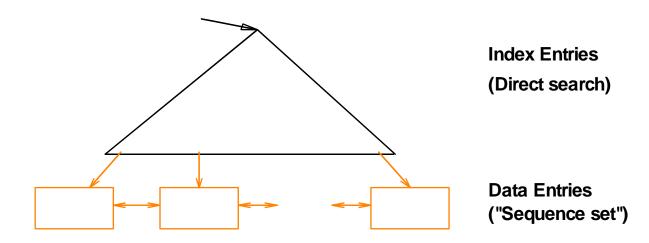

... Then Deleting 42*, 51*, 97*

❖ Note that 51* appears in index levels, but not in leaf!

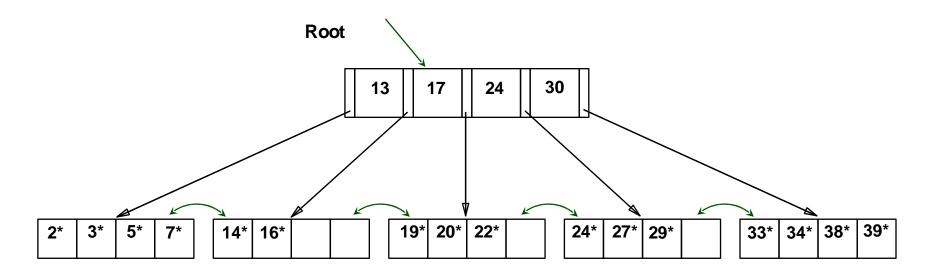

B+Tree: Most Widely Used Index

- \bigstar Insert/delete at $\log_F N$ cost; keep tree *height-balanced*. (F = fanout, N = # leaf pages)
- * Minimum 50% occupancy (except for root). Each node contains $\mathbf{d} <= \underline{m} <= 2\mathbf{d}$ entries. The parameter \mathbf{d} is called the *order* of the tree.
- Supports equality and range-searches efficiently.

Example B + Tree

- Search begins at root, and key comparisons direct it to a leaf (as in ISAM).
- \diamond Search for 5*, 15*, all data entries >= 24* ...

 \clubsuit Based on the search for 15*, we know it is not in the tree!

B+Trees in Practice

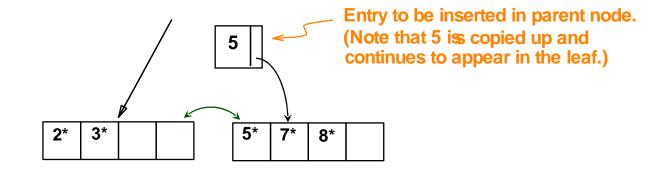

- ❖ Typical order: 100. Typical fill-factor: 67
 - average fanout = 133
- **❖** Typical capacities:
 - Height 4: $133^4 = 312,900,700$ records
 - Height 3: $133^3 = 2,352,637$ records
- Can often hold top levels in buffer pool:
 - Level 1 = 1 page = 8 Kbytes
 - Level 2 = 133 pages = 1 Mbyte
 - Level 3 = 17,689 pages = 133 MBytes

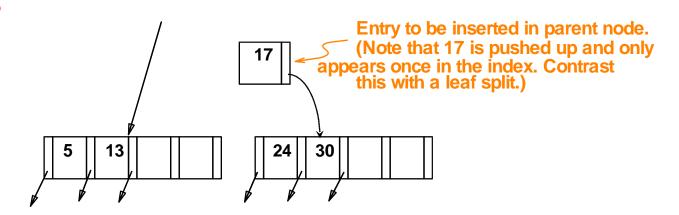

Inserting a Data Entry into a B+Tree

- \clubsuit Find correct leaf L.
- \diamond Put data entry onto L.
 - If L has enough space, done!
 - Else, must *split L* (*into L and a new node L2*)
 - Redistribute entries evenly, <u>copy up</u> middle key.
 - Insert index entry pointing to *L*2 into parent of *L*.
- This can happen recursively
 - To split index node, redistribute entries evenly, but **push up** middle key. (Contrast with leaf splits.)
- Splits "grow" tree; root split increases height.
 - Tree growth: gets <u>wider</u> or <u>one level taller at top.</u>

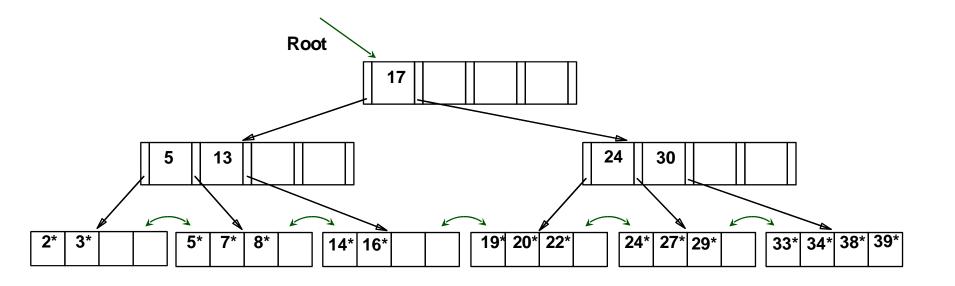

Inserting 8* into Example B+Tree

- Observe how minimum occupancy is guaranteed in both leaf and index pg splits.
- **❖** Note difference between *copy-up* and *push-up*; be sure you understand the reasons for this.

Example B+Tree After Inserting 8*

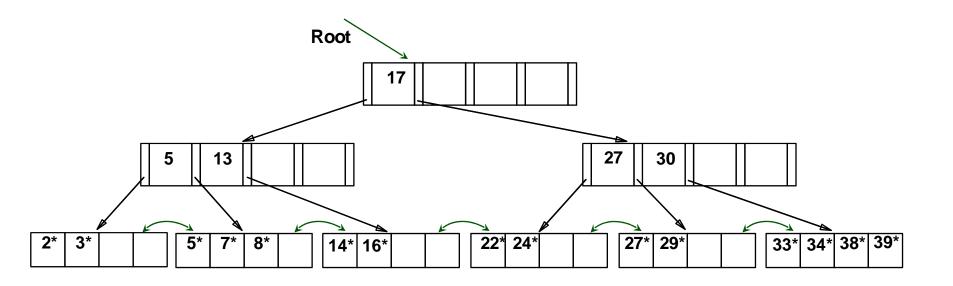

- Notice that root was split, leading to increase in height.
- ❖ In this example, we can avoid split by re-distributing entries; however, this is usually not done in practice.

Deleting a Data Entry from a B+Tree

- \diamond Start at root, find leaf L where entry belongs.
- Remove the entry.
 - If L is at least half-full, done!
 - If L has only **d-1** entries,
 - Try to re-distribute, borrowing from *sibling* (*adjacent* node with same parent as L).
 - If re-distribution fails, <u>merge</u> *L* and sibling.
- \clubsuit If merge occurred, must delete entry (pointing to L or sibling) from parent of L.
- Merge could propagate to root, decreasing height.

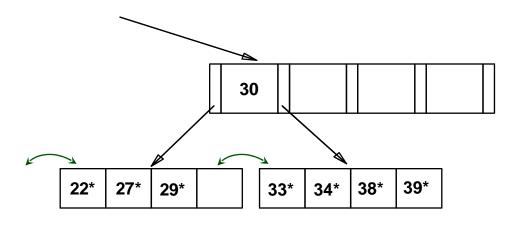

Example Tree After (Inserting 8*, then) Deleting 19* and 20* ...

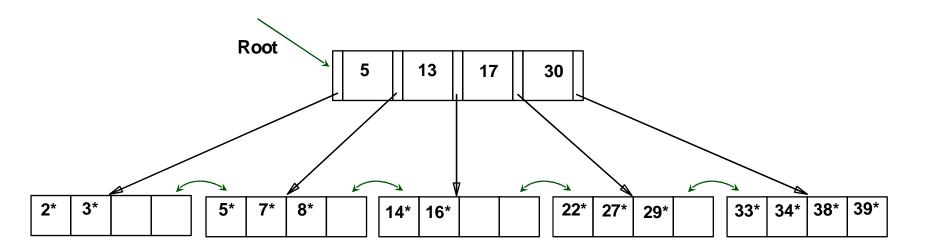

- ♦ Deleting 19* is easy.
- ❖ Deleting 20* is done with re-distribution. Notice how middle key is *copied up*.

... And Then Deleting 24*

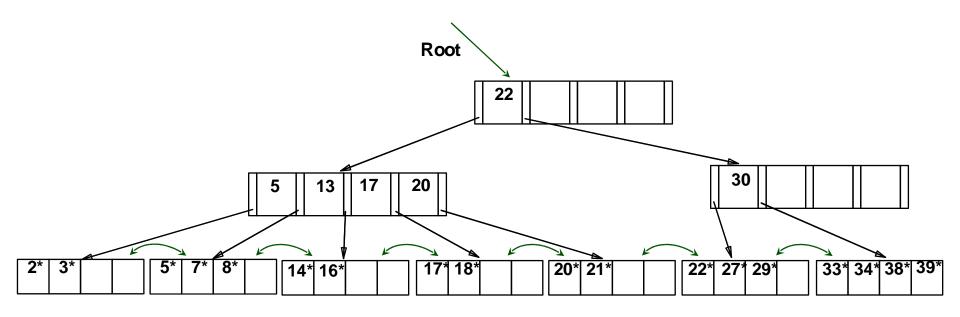

- Must merge.
- ♦ Observe `toss' of index entry (on right), and `pull down' of index entry (below).

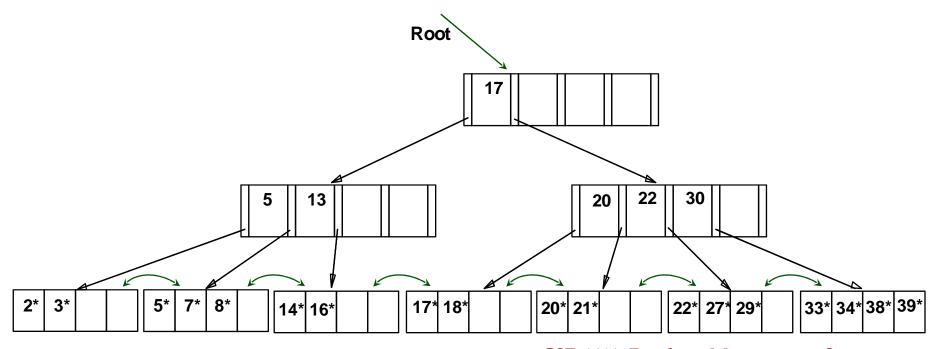

Example of Non-leaf Re-distribution

- Tree is shown below during deletion of 24*. (What could be a possible initial tree?)
- ❖ In contrast to previous example, can re-distribute entry from left child of root to right child.

After Re-distribution

- ❖ Intuitively, entries are re-distributed by `pushing through' the splitting entry in the parent node.
- ❖ It suffices to re-distribute index entry with key 20; we've re-distributed 17 as well for illustration.

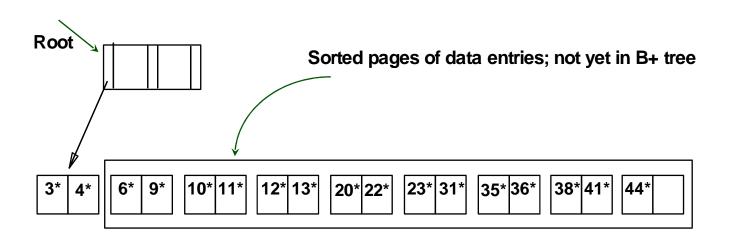

Prefix Key Compression

- ❖ Important to increase fan-out. (Why?)
- * Key values in index entries only `direct traffic'; can often compress them.
 - E.g., If we have adjacent index entries with search key values Dannon Yogurt, David Smith and Devarakonda Murthy, we can abbreviate David Smith to *Dav*. (The other keys can be compressed too ...)
 - Is this correct? Not quite! What if there is a data entry Davey Jones? (Can only compress David Smith to Davi)
 - In general, while compressing, must leave each index entry greater than every key value (in any subtree) to its left.
- ❖ Insert/delete must be suitably modified.

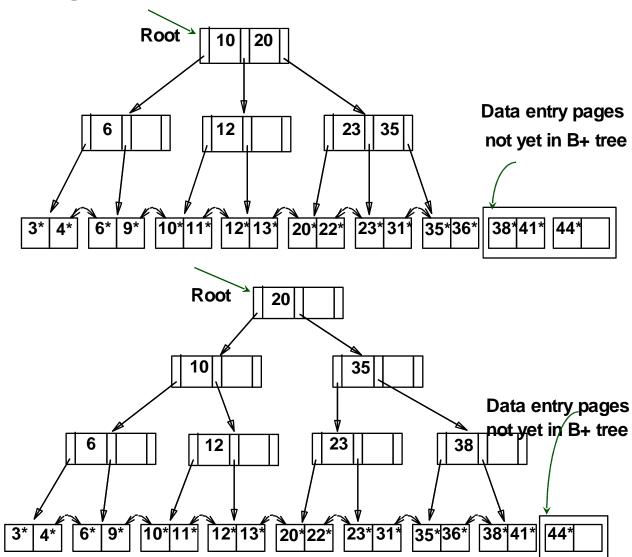

Bulk Loading of a B+Tree

- ❖ If we have a large collection of records, and we want to create a B+ tree on some field, doing so by repeatedly inserting records is very slow.
- * Bulk Loading can be done much more efficiently.
- * Initialization: Sort all data entries, insert pointer to first (leaf) page in a new (root) page.

Bulk Loading (Cont.)

- **❖** Index entries for leaf pages always entered into rightmost index page just above leaf level. When this fills up, it splits. (Split may go up right-most path to the root.)
- Much faster than repeated inserts, especially when one considers locking!

Summary of Bulk Loading

- Option 1: multiple inserts.
 - Slow.
 - Does not give sequential storage of leaves.
- ❖ Option 2: *Bulk Loading*
 - Has advantages for concurrency control.
 - Fewer I/Os during build.
 - Leaves will be stored sequentially (and linked, of course).
 - Can control "fill facto" on pages.

A Note on 'Order'

- ❖ Order (d) concept replaced by physical space criterion in practice (`at least half-full').
 - Index pages can typically hold many more entries than leaf pages.
 - Variable sized records and search keys mean differnt nodes will contain different numbers of entries.
 - Even with fixed length fields, multiple records with the same search key value (duplicates) can lead to variable-sized data entries (if we use Alternative (3)).

Summary

- * Tree-structured indexes are ideal for range-searches, also good for equality searches.
- **❖** ISAM is a static structure.
 - Only leaf pages modified; overflow pages needed.
 - Overflow chains can degrade performance unless size of data set and data distribution stay constant.
- ❖ B+ tree is a dynamic structure.
 - Inserts/deletes leave tree height-balanced; log F N cost.
 - High fanout (F) means depth rarely more than 3 or 4.
 - Almost always better than maintaining a sorted file.

Summary (Cont.)

- ❖ B+ Trees:
 - Typically, 67% occupancy on average.
 - Usually preferable to ISAM, modulo *locking* considerations; adjusts to growth gracefully.
 - If data entries are data records, splits can change rids!
- * Key compression increases fanout, reduces height.
- * Bulk loading can be much faster than repeated inserts for creating a B+ tree on a large data set.
- Most widely used index in database management systems because of its versatility. One of the most optimized components of a DBMS.
