## AVL Trees

## CSE 2011

Fall 2009

## AVL Trees

- AVL trees are balanced.
- An AVL Tree is a binary search tree such that for every internal node v of T , the heights of the
 children of $v$ can differ by at most 1.

An example of an AVL tree where the heights are shown next to the nodes

## Height of an AVL Tree

- Proposition: The height of an AVL tree T storing n keys is $\mathrm{O}(\log n)$.

Proof:

- Find $\mathbf{n}(\mathbf{h})$ : the minimum number of internal nodes of an AVL tree of height $h$
- We see that $n(1)=1$ and $n(2)=2$
- For $h \geq 3$, an AVL tree of height $h$ contains the root node, one AVL subtree of height $\mathrm{h}-1$ and the other AVL subtree of height $h-2$.
- i.e. $n(h)=1+n(h-1)+n(h-2)$

## Height of an AVL Tree (2)

- Knowing $n(h-1)>n(h-2)$, we get $n(h)>2 n(h-2)$

$$
\begin{aligned}
& n(h)>2 n(h-2) \\
& n(h)>4 n(h-4) \\
& \ldots \\
& n(h)>2^{i} n(h-2 i)
\end{aligned}
$$

- Solving the base case we get: $n(h) \geq 2^{h / 2-1}$
- Taking logarithms: $\mathrm{h}<2 \log \mathrm{n}(\mathrm{h})+2$
- Thus the height of an AVL tree is $\mathrm{O}(\log \mathrm{n})$

## Insertion in an AVL Tree

- Insertion is as in a binary search tree
- Always done by expanding an external node.
- Example:

before insertion

after insertion

## Insertion (2)

- A binary search tree T is called balanced if for every node $v$, the height of v's children differ by at most 1.
- Inserting a node into an AVL tree involves performing insertAtExternal(w, e) on T, which changes the heights of some of the nodes in T .
- If an insertion causes T to become unbalanced, we travel up the tree from the newly created node $w$ until we find the first node $z$ that is unbalanced.
- $y=$ child of $z$ with higher height (Note: $y=$ ancestor of $w$ )
- $x=$ child of $y$ with higher height
(Note: $x=$ ancestor of $w$ or $x=w$ )
- Since $z$ became unbalanced by an insertion in the subtree rooted at its child $y$, height $(\mathrm{y})=\operatorname{height}($ sibling $(\mathrm{y}))+2$

## Insertion: rebalancing

- Now to rebalance...
- To rebalance the subtree rooted at $z$, we must perform a restructuring
- We rename $x, y$, and $z$ to $a, b$, and $c$ based on the order of the nodes in an in-order traversal (4 possible mappings)
- $z$ is replaced by $b$, whose children are now a and $c$ whose children, in turn, consist of the four other subtrees formerly children of $x, y$, and $z$.

## Trinode Restructuring

- let $(a, b, c)$ be an inorder listing of $x, y, z$
- perform the rotations needed to make $b$ the topmost node of the three

## Insertion Example

unbalanced...

...balanced

## Restructuring

Single rotations

## Restructuring (2)

## Restructure Algorithm

## Algorithm restructure $(x)$ :

Input: A node $x$ of a binary search tree $T$ that has both a parent $y$ and a grandparent $z$
Output: Tree T restructured by a rotation (either
single or double) involving nodes $\mathrm{x}, \mathrm{y}$, and z .

1. Let ( $a, b, c$ ) be an inorder listing of the nodes $x, y$, and $z$, and let (TO, T1, T2, T3) be an inorder listing of the the four subtrees of $x, y$, and $z$, not rooted at $x, y$, or $z$.
2. Replace the subtree rooted at $z$ with a new subtree rooted at $b$
3. Let $a$ be the left child of $b$ and let T0, T1 be the left and right subtrees of a, respectively.
4. Let $c$ be the right child of $b$ and let T2, T3 be the left and right subtrees of $c$, respectively.

## Cut/Link Restructure Algorithm

- Any tree that needs to be balanced can be grouped into 7 parts: $x, y, z$, and the 4 trees anchored at the children of those nodes $\left(T_{0}, T_{1}, T_{2}, T_{3}\right)$

## Cut/Link Restructure Algorithm

- Number the 7 parts by doing an inorder traversal
- $x, y$, and $z$ are now renamed based upon their order within the inorder traversal

## Cut/Link Restructure Algorithm

- Now we can re-link these subtrees to the main tree.
- Link in node 4 (b) where the subtree's root formerly

## Cut/Link Restructure Algorithm

- Link in nodes 2 (a) and 6 (c) as children of node 4.

## Cut/Link Restructure Algorithm

- Finally, link in subtrees 1 and 3 as the children of node 2 , and subtrees 5 and 7 as the children of 6 .

## Analysis of Cut/Link Restructure Algorithm

- This algorithm for restructuring has the exact same effect as using the four rotation cases discussed earlier.
- Advantages: no case analysis, more elegant
- Disadvantage: can be more code to write
- Same time complexity

## Removal

- Performing a removeExternal(w) can cause T to become unbalanced.
- Let $z$ be the first unbalanced node encountered while travelling up the tree from w.
- $y=$ child of $z$ with higher height ( $y \neq$ ancestor of $w$ )
- $x=$ child of $y$ with higher height, or either child if two children of $y$ have the same height.
- Perform operation restructure(x) to restore balance at the subtree rooted at $z$.
- As this restructuring may upset the balance of another node higher in the tree, we must continue checking for balance until the root of T is reached.

## Removal Example

Whew, balanced!

## Removal Example (2)

Next time ...

- Heaps (8.3)
