

# Examples of how a Functional Program can be Developed

## From

- an existing recursive program
- analysis of input and output diagrams

# Transpose a 2d-Matrix – 1

◇ 2-d matrix is represented as a list of rows all of the same length

◇ For example

**1 2 3**  
**4 5 6**     -->    **(( 1 2 3 ) ( 4 5 6 ) ( 7 8 9 ))**  
**7 8 9**

◇ The transpose (swap rows and columns) of the above is

**1 4 7**  
**2 5 8**     -->    **(( 1 4 7 ) ( 2 5 8 ) ( 3 6 9 ))**  
**3 6 9**

## Transpose a 2d-Matrix – 2

```
(defun trans ( theMatrix )
  (cond ( ( null ( car theMatrix ) ) nil )
        ( t ( cons ( firstOfEach theMatrix )
                    ( trans (restOfEach theMatrix ) )))
  ))
```

```
(defun firstOfEach ( theMatrix ) ; Extract first of each row
  (cond ( ( null theMatrix ) nil )
        ( t ( cons ( caar theMatrix )
                    ( firstOfEach ( cdr theMatrix ) )))
  ))
```

```
(defun restOfEach ( theMatrix ) ; remove first of each row
  (cond ( ( null theMatrix ) nil )
        ( t ( cons ( cdar theMatrix )
                    ( restOfEach ( cdr theMatrix ) )))
  ))
```

## Transpose a 2d-Matrix – 3

- ◇ Analysis of the transpose program shows that **trans** invokes **firstOfEach** to every decreasing rows (**restOfEach**)
- ◇ This is what **maplist** does
- ◇ So a first pass of **trans** becomes

```
(defun trans (theMatrix)
  (maplist 'firstOfEach theMatrix)
)
```

» **(trans '( (1 2 3) (4 5 6) (7 8 9) )) ==> ((1 4 7) (4 7) (7))**
- ◇ What went wrong?

## Transpose a 2d-Matrix – 4

- ◇ Put a print statement in **firstOfEach**

```
(defun firstOfEach (theMatrix) ; Extract first of each row
  (print theMatrix)
  (cond ((null theMatrix) nil)
        (t (cons (caar theMatrix) (firstOfEach (cdr theMatrix))))
  ))
```

- ◇ The output is

```
((1 2 3) (4 5 6) (7 8 9)) ; first call from maplist
((4 5 6) (7 8 9)) ; recursion
((7 8 9))
NIL
((4 5 6) (7 8 9)) ; second call from maplist
((7 8 9)) ; recursion
NIL
((7 8 9)) ; third call from maplist
NIL ; recursion
((1 4 7) (4 7) (7)) ; the answer
```

## Transpose a 2d-Matrix – 5

- ◇ **maplist** is removing the rows not the first of each row because **maplist** is working on the matrix a row at a time
  - » **Input is ( (1 2 3) (4 5 6) (7 8 9) ) -- one list of rows**
- ◇ We want **maplist** to work on each row
  - » **Input should be (1 2 3) (4 5 6) (7 8 9) -- three lists**
  - » **This is a common problem we want to remove the outer parenthesis**
  - » **Recall that **apply** removes the outer level of parenthesis when invoking a function on arguments**
- ◇ Thus **trans** becomes

```
(defun trans (theMatrix)
  (apply 'maplist 'firstOfEach theMatrix)
)
```

## Transpose a 2d-Matrix – 6

- ◇ We try **trans** and get an error message such as  
**Error: Expected 1 args but received 3 args**  
**Fast links are on: do (si::use-fast-links nil) for debugging**  
**Error signalled by MAPLIST.**  
**Broken at FIRSTOFEACH**

## Transpose a 2d-Matrix – 7

- ◇ Ah! now we have one argument for each row as input to **firstOfEach** but the function expects a single argument – a list of rows
  - » Use the keyword **&rest** to gather all the arguments into one.

```
(defun firstOfEach ( &rest theMatrix )  
  ( cond ( ( null theMatrix ) nil )  
        ( t ( cons ( caar theMatrix )  
                    ( firstOfEach ( cdr theMatrix ) ) ) ) )  
  )
```

## Transpose a 2d-Matrix – 8

- ◇ We try **trans** and get infinite recursion – the print statement shows the following for the first few lines

**((1 2 3) (4 5 6) (7 8 9))**

**(((4 5 6) (7 8 9)))**

**; list nested one deeper**

**(NIL)**

**(NIL)**

**(NIL) goes on forever**

## Transpose a 2d-Matrix – 9

- ◇ Each recursive call to **firstOfEach** adds a layer of parenthesis
  - » **Again a common error – we need to remove the parenthesis before the recursive call – use **apply****

```
(defun firstOfEach ( &rest theMatrix )
  ( cond ( ( null theMatrix ) nil )
        ( t ( cons ( caar theMatrix )
                    ( apply 'firstOfEach
                           ( cdr theMatrix ) ) ) )
        )
  )
```

## Transpose a 2d-Matrix – 10

- ◇ **trans** now works with the upper level being a functional but **firstOfEach** is still recursive

```
(defun trans ( theMatrix )  
  ( apply 'maplist 'firstOfEach theMatrix )  
)
```

```
(defun firstOfEach ( &rest theMatrix )  
  ( cond ( ( null theMatrix ) nil )  
        ( t ( cons ( caar theMatrix )  
                    ( apply 'firstOfEach  
                          ( cdr theMatrix ) ) ) ) )  
)
```

## Transpose a 2d-Matrix – 11

- ◇ Notice that **firstOfEach** takes the first item from each sublist

```
(defun firstOfEach (&rest theMatrix)
  (cond ((null theMatrix) nil)
        (t (cons (caar theMatrix) (apply 'firstOfEach
                                           (cdr theMatrix))))))
))
```

- ◇ **car** gives the first of a list and **mapcar** will apply it to every sublist in a list and collect the results in a list so we have

```
(defun firstOfEach ( &rest theMatrix )
  ( mapcar 'car theMatrix )
)
```

## Transpose a 2d-Matrix – 12

- ◇ We have two functionals for the solution

```
(defun trans ( theMatrix )  
  ( apply 'maplist 'firstOfEach theMatrix )  
)
```

```
(defun firstOfEach ( &rest theMatrix )  
  ( mapcar 'car theMatrix )  
)
```

- ◇ Using lambda we can eliminate **firstOfEach**

```
(defun trans ( theMatrix )  
  ( apply 'maplist #'( lambda ( &rest theMatrix )  
                      ( mapcar 'car theMatrix ) )  
          theMatrix )  
)
```

## Transpose a 2d-Matrix – 13

- ◇ But nothing beats creative insight and knowledge of available operations
- ◇ The following gives the transpose

```
(defun trans ( theMatrix )  
  (apply 'mapcar 'list theMatrix )  
)
```

# All pairs functional – 1

- ◇ We want the following functional

**allPairs** :  $\langle \langle a, b, c \rangle , \langle 1, 2, 3, 4 \rangle \rangle$       **input**

$\implies$

$\langle \langle a, 1 \rangle , \langle a, 2 \rangle , \langle a, 3 \rangle , \langle a, 4 \rangle ,$       **output**  
 $\langle b, 1 \rangle , \langle b, 2 \rangle , \langle b, 3 \rangle , \langle b, 4 \rangle ,$   
 $\langle c, 1 \rangle , \langle c, 2 \rangle , \langle c, 3 \rangle , \langle c, 4 \rangle \rangle$

- ◇ We make use of the ‘picture’ of the input and output to infer a functional solution

## All pairs functional – 2

◇ Looking at the functionals in the library it seems that distribution may be useful

◇ Lets try it

**distl** : < <a, b, c> , <1, 2, 3, 4> >

==>

< << a, b, c >, 1 > , << a, b, c >, 2 > , << a, b, c >, 3 > ... >

◇ Looks good but we want to distribute second argument over the first

◇ **rev** could be used but we have **distr**

**distr** : < <a, b, c> , <1, 2, 3, 4> >

==>

< < 1, < a, b, c > > , < 2, < a, b, c > > , < 3, < a, b, c > ... >

## All pairs functional – 3

◇ We have

**distr : < <a, b, c> , <1, 2, 3, 4> >**

**==>**

**< < 1, < a, b, c > > , < 2, < a, b, c > > , < 3, < a, b, c > ... >**

◇ If we distribute ‘right’ the numbers over each list we have

**< < <a , 1> , < b, 1> , <c, 1 > > ... >**

◇ But examining the output we see that ‘a’ is repeated first not the “1”

**< <a,1> , <a,2> , <a,3> , <a,4> ,      output  
<b,1> , <b,2> , <b,3> , <b,4> ,  
<c,1> , <c,2> , <c,3> , <c,4> >**

## All pairs functional – 4

- ◇ What we need to do is to reverse the order of the arguments so the letters are distributed first

**distr o [ 2 , 1 ] : <<a, b, c> , <1, 2, 3, 4> >**

**==>**

**<< a, < 1, 2, 3, 4 > > , < b, < 1, 2, 3, 4 > > ... >**

- ◇ Now if we apply distribute left to each sublist we have

**(α distl) : << a, < 1, 2, 3, 4 > > ,**

**< b, < 1, 2, 3, 4 > > ... >**

**==>**

**<<< a, 1 > , < a, 2 > , < a, 3 > , < a, 4 > >**

**<< b, 1 > ... >**

## All pairs functional – 5

- ◇ So far we have

$(\alpha \text{ distl}) \circ \text{distr} \circ [2, 1]$

$\implies$

$\langle \langle \langle a, 1 \rangle, \langle a, 2 \rangle, \langle a, 3 \rangle, \langle a, 4 \rangle \rangle, \langle \langle b, 1 \rangle \dots \rangle$

- ◇ But we have the pairs nested within an extra pair of lists

- ◇ What we need to do is to **reduce** the lists into one using **append**

$(/ \text{ append} ) :$

$\langle \langle \langle a, 1 \rangle, \langle a, 2 \rangle, \langle a, 3 \rangle, \langle a, 4 \rangle \rangle, \langle \langle b, 1 \rangle \dots \rangle$

$\implies$

$\langle \langle a, 1 \rangle, \langle a, 2 \rangle, \langle a, 3 \rangle, \langle a, 4 \rangle, \langle b, 1 \rangle \dots \rangle$

## All pairs functional – 6

◇ So the final function definition is

**allPairs ::= (/ append ) o (α distl) o distr o [ 2 , 1 ]**

◇ Other orderings are possible using other combinations of swapping or not swapping the initial lists and using left or right distribution for the second distribution

**allPairs ::= (/ append ) o (α distr) o distr o [ 2 , 1 ]**

**allPairs ::= (/ append ) o (α distl) o distr**

**allPairs ::= (/ append ) o (α distr) o distr**
