

# Motion Models (cont)

# Odometry Motion Model

- ▶ the key to computing  $p(x_t | u_t, x_{t-1})$  for the odometry motion model is to remember that the robot has an internal estimate of its pose

# Odometry Motion Model

- ▶ the key to computing  $p(x_t | u_t, x_{t-1})$  for the odometry motion model is to remember that the robot has an internal estimate of its pose

robot's internal poses

# Odometry Motion Model

- ▶ the control vector is made up of the three motions made by the robot

$$u_t = \begin{pmatrix} \delta_{trans} \\ \delta_{rot1} \\ \delta_{rot2} \end{pmatrix}$$

- ▶ use the robot's internal pose estimates to compute the  $\delta$

$$\delta_{trans} = \sqrt{(\bar{x}' - \bar{x})^2 + (\bar{y}' - \bar{y})^2}$$

$$\delta_{rot1} = \text{atan2}(\bar{y}' - \bar{y}, \bar{x}' - \bar{x}) - \bar{\theta}$$

$$\delta_{rot2} = \bar{\theta}' - \bar{\theta} - \delta_{rot1}$$

# Odometry Motion Model

- ▶ use the true poses to compute the  $\delta$

$$\hat{\delta}_{trans} = \sqrt{(x'-x)^2 + (y'-y)^2}$$

$$\hat{\delta}_{rot1} = \text{atan2}(y'-y, x'-x) - \theta$$

$$\hat{\delta}_{rot2} = \theta' - \theta - \hat{\delta}_{rot1}$$

- ▶ as with the velocity motion model, we have to solve the inverse kinematics problem here

# Odometry Motion Model

- ▶ recall the noise model

$$\hat{\delta}_{trans} - \delta_{trans} = \mathcal{E}_{\alpha_3 \hat{\delta}_{trans}^2 + \alpha_4 (\hat{\delta}_{rot1}^2 + \hat{\delta}_{rot2}^2)}$$

$$\hat{\delta}_{rot1} - \delta_{rot1} = \mathcal{E}_{\alpha_1 \hat{\delta}_{rot1}^2 + \alpha_2 \hat{\delta}_{trans}^2}$$

$$\hat{\delta}_{rot2} - \delta_{rot2} = \mathcal{E}_{\alpha_1 \hat{\delta}_{rot2}^2 + \alpha_2 \hat{\delta}_{trans}^2}$$

which makes it easy to compute the probabilities of observing the differences in the  $\delta$

$$p_1 = \text{prob}(\hat{\delta}_{trans} - \delta_{trans}, \alpha_3 \hat{\delta}_{trans}^2 + \alpha_4 (\hat{\delta}_{rot1}^2 + \hat{\delta}_{rot2}^2))$$

$$p_2 = \text{prob}(\hat{\delta}_{rot1} - \delta_{rot1}, \alpha_1 \hat{\delta}_{rot1}^2 + \alpha_2 \hat{\delta}_{trans}^2)$$

$$p_3 = \text{prob}(\hat{\delta}_{rot2} - \delta_{rot2}, \alpha_1 \hat{\delta}_{rot2}^2 + \alpha_2 \hat{\delta}_{trans}^2)$$

# Calculating the Posterior Given $\mathbf{x}$ , $\mathbf{x}'$ , and $\mathbf{u}$

---

I. Algorithm `motion_model_odometry(x,x',u)`

2.  $\delta_{trans} = \sqrt{(\bar{x}' - \bar{x})^2 + (\bar{y}' - \bar{y})^2}$

3.  $\delta_{rot1} = \text{atan2}(\bar{y}' - \bar{y}, \bar{x}' - \bar{x}) - \bar{\theta}$

4.  $\delta_{rot2} = \bar{\theta}' - \bar{\theta} - \delta_{rot1}$

odometry values ( $\mathbf{u}$ )

5.  $\hat{\delta}_{trans} = \sqrt{(x' - x)^2 + (y' - y)^2}$

6.  $\hat{\delta}_{rot1} = \text{atan2}(y' - y, x' - x) - \bar{\theta}$

7.  $\hat{\delta}_{rot2} = \theta' - \theta - \hat{\delta}_{rot1}$

values of interest ( $\mathbf{x}, \mathbf{x}'$ )

8.  $p_1 = \text{prob}(\delta_{rot1} - \hat{\delta}_{rot1}, \alpha_1 \hat{\delta}_{rot1}^2 + \alpha_2 \hat{\delta}_{trans}^2)$

9.  $p_2 = \text{prob}(\delta_{trans} - \hat{\delta}_{trans}, \alpha_3 \hat{\delta}_{trans}^2 + \alpha_4 (\hat{\delta}_{rot1}^2 + \hat{\delta}_{rot2}^2))$

10.  $p_3 = \text{prob}(\delta_{rot2} - \hat{\delta}_{rot2}, \alpha_1 \hat{\delta}_{rot2}^2 + \alpha_2 \hat{\delta}_{trans}^2)$

II. return  $p_1 \cdot p_2 \cdot p_3$

# Recap

## ▶ velocity motion model

- ▶ control variables were linear velocity, angular velocity about ICC, and final angular velocity about robot center

# Recap

- ▶ odometric motion model
  - ▶ control variables were derived from odometry
    - ▶ initial rotation, translation, final rotation

# Recap

- ▶ for both models we assumed the control inputs  $u_t$  were noisy
- ▶ the noise models were assumed to be zero-mean additive with a specified variance

$$\begin{pmatrix} \hat{v} \\ \hat{\omega} \end{pmatrix} = \begin{pmatrix} v \\ \omega \end{pmatrix} + \begin{pmatrix} v_{\text{noise}} \\ \omega_{\text{noise}} \end{pmatrix}$$

actual      commanded      noise  
velocity      velocity

$$\text{var}(v_{\text{noise}}) = \alpha_1 v^2 + \alpha_2 \omega^2$$

$$\text{var}(\omega_{\text{noise}}) = \alpha_3 v^2 + \alpha_4 \omega^2$$

# Recap

- ▶ for both models we assumed the control inputs  $u_t$  were noisy
- ▶ the noise models were assumed to be zero-mean additive with a specified variance

$$\begin{pmatrix} \hat{\delta}_{trans} \\ \hat{\delta}_{rot1} \\ \hat{\delta}_{rot2} \end{pmatrix} = \begin{pmatrix} \delta_{trans} \\ \delta_{rot1} \\ \delta_{rot2} \end{pmatrix} + \begin{pmatrix} \delta_{trans,noise} \\ \delta_{rot1,noise} \\ \delta_{rot2,noise} \end{pmatrix}$$

actual      commanded      noise  
motion      motion

$$\text{var}(\delta_{trans,noise}) = \alpha_3 \hat{\delta}_{trans}^2 + \alpha_4 (\hat{\delta}_{rot1}^2 + \hat{\delta}_{rot2}^2)$$

$$\text{var}(\delta_{rot1,noise}) = \alpha_1 \hat{\delta}_{rot1}^2 + \alpha_2 \hat{\delta}_{trans}^2$$

$$\text{var}(\delta_{rot2,noise}) = \alpha_1 \hat{\delta}_{rot2}^2 + \alpha_2 \hat{\delta}_{trans}^2$$

# Recap

- ▶ for both models we studied how to derive  $p(x_t | u_t, x_{t-1})$ 
  - ▶ given
    - ▶  $x_{t-1}$       current pose
    - ▶  $u_t$         control input
    - ▶  $x_t$         new pose
  - find the probability density that the new pose is generated by the current pose and control input
- ▶ required inverting the motion model to compare the *actual* with the *commanded* control parameters

# Recap

- ▶ for both models we studied how to sample from  $p(x_t | u_t, x_{t-1})$ 
  - ▶ given
    - ▶  $x_{t-1}$       current pose
    - ▶  $u_t$       control input
  - generate a random new pose  $x_t$  consistent with the motion model
- ▶ sampling from  $p(x_t | u_t, x_{t-1})$  is often easier than calculating  $p(x_t | u_t, x_{t-1})$  directly because only the forward kinematics are required

# Recap

- ▶ see section 5.5 of the textbook for an extension of the motion models to include a map of the environment
- ▶ in particular notice the numerous assumptions and approximations that need to be made to make the computations tractable
  - ▶ also, pay attention to the consequences of making such assumptions and approximations
