Day 21

Kalman Filter Examples

Tank of Water

static level

plant model
$$X_t = X_{t-1}$$

measurement model

$$z_t = x_t + \delta_t$$

Tank of Water

filling at a (noisy) constant rate and we do not care about the rate

plant model
$$x_t = x_{L,t-1} + \Delta x_L + \mathcal{E}_t$$

measurement model $z_t = x_t + \delta_t$

u_t is the change in the water level that occurred from time *t*-1
 to *t*

Tank of Water

filling at a (noisy) constant rate and we want to estimate the rate

measurement model

$$z_t = \underbrace{\begin{bmatrix} 1 & 0 \end{bmatrix}}_{C_t} x_t + \delta_t$$

Projectile Motion

 projectile launched from some initial point with some initial velocity under the influence of gravity (no drag)

$$x(t) = x_0 + v_x t$$

$$y(t) = y_0 + v_y t - \frac{1}{2} g t^2$$

$$v_x(t) = v_x$$

$$v_y(t) = v_y - g t$$

Projectile Motion

• convert the continuous time equations to discrete recurrence relations for some time step Δt

$$x_{t} = x_{t-1} + v_{x,t-1}\Delta t$$

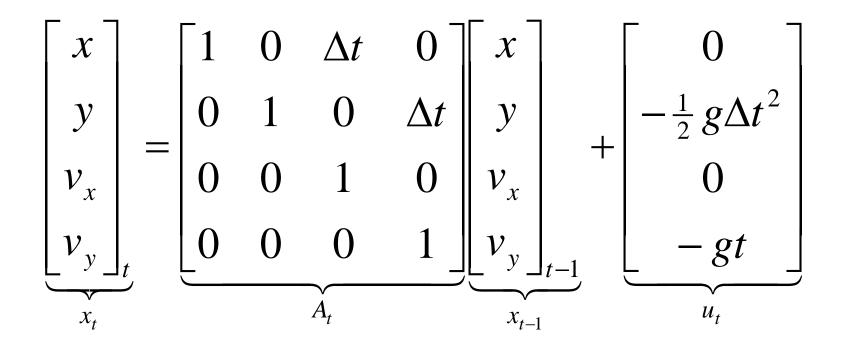

$$y_{t} = y_{t-1} + v_{y,t-1}\Delta t - \frac{1}{2}g\Delta t^{2}$$

$$v_{x,t} = v_{x,t-1}$$

$$v_{y,t} = v_{y,t-1} - g\Delta t$$

Projectile Motion

rewrite in matrix form

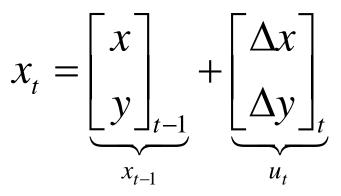

Omnidirectional Robot

- an omnidirectional robot is a robot that can move in any direction (constrained in the ground plane)
 - http://www.youtube.com/watch?v=DPz-ullMOqc
 - http://www.engadget.com/2011/07/09/curtis-boirums-robotic-carmakes-omnidirectional-dreams-come-tr/
- if we are not interested in the orientation of the robot then its state is simply its location

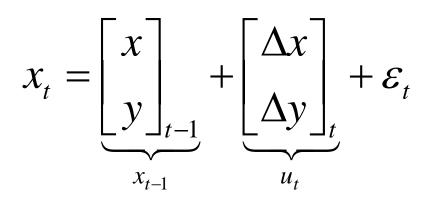

$$x_t = \begin{bmatrix} x \\ y \end{bmatrix}_t$$

Omnidirectional Robot

 a possible choice of motion control is simply a change in the location of the robot

with noisy control inputs

Differential Drive

- recall that we developed two motion models for a differential drive
 - using the velocity model, the control inputs are

$$u_{t} = \begin{pmatrix} v_{t} \\ \omega_{t} \end{pmatrix} + \begin{pmatrix} \mathcal{E}_{\alpha_{1}v_{t}^{2} + \alpha_{2}\omega_{t}^{2}} \\ \mathcal{E}_{\alpha_{3}v_{t}^{2} + \alpha_{4}\omega_{t}^{2}} \end{pmatrix}$$

Differential Drive

 using the velocity motion model the discrete time forward kinematics are

$$x_{t} = \begin{pmatrix} x' \\ y' \\ \theta' \end{pmatrix} = \begin{pmatrix} x_{c} + \frac{v}{\omega}\sin(\theta + \omega\Delta t) \\ y_{c} - \frac{v}{\omega}\cos(\theta + \omega\Delta t) \\ \theta + \omega\Delta t \end{pmatrix}$$
$$= \begin{pmatrix} x - \frac{v}{\omega}\sin\theta + \frac{v}{\omega}\sin(\theta + \omega\Delta t) \\ y + \frac{v}{\omega}\cos\theta - \frac{v}{\omega}\cos(\theta + \omega\Delta t) \\ \theta + \omega\Delta t \end{pmatrix}$$
Eqs 5.9

Differential Drive

- there are two problems when trying to use the velocity motion model in a Kalman filter
 - 1. the plant model is not linear in the state and control

$$x_{t} = \begin{pmatrix} x - \frac{v_{t}}{\omega_{t}} \sin \theta + \frac{v_{t}}{\omega_{t}} \sin(\theta + \omega_{t} \Delta t) \\ y + \frac{v_{t}}{\omega_{t}} \cos \theta - \frac{v_{t}}{\omega_{t}} \cos(\theta + \omega_{t} \Delta t) \\ \theta + \omega_{t} \Delta t \end{pmatrix}$$

2. it is not clear how to describe the control noises as a plant covariance matrix

$$u_{t} = \begin{pmatrix} v_{t} \\ \omega_{t} \end{pmatrix} + \begin{pmatrix} \mathcal{E}_{\alpha_{1}v_{t}^{2} + \alpha_{2}\omega_{t}^{2}} \\ \mathcal{E}_{\alpha_{3}v_{t}^{2} + \alpha_{4}\omega_{t}^{2}} \end{pmatrix}$$

Measurement Model

- there are potentially other problems
 - any non-trivial measurement model will be non-linear in terms of the state
- consider using the known locations of landmarks in a measurement model

Landmarks

- a landmark is literally a prominent geographic feature of the landscape that marks a known location
- in common usage, landmarks now include any fixed easily recognizable objects
 - e.g., buildings, street intersections, monuments
- for mobile robots, a landmark is any fixed object that can be sensed

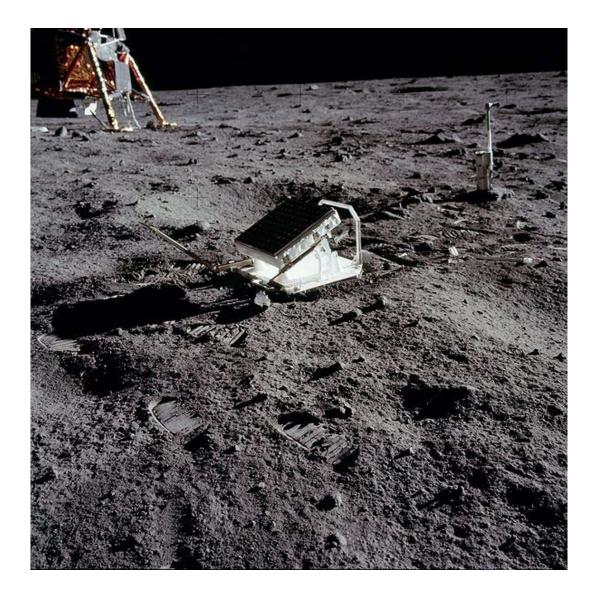

Landmarks for Mobile Robots

- visual
 - artificial or natural
- retro-reflective
- beacons
 - LORAN (Long Range Navigation): terrestrial radio; now being phased out
 - GPS: satellite radio
- acoustic
- scent?

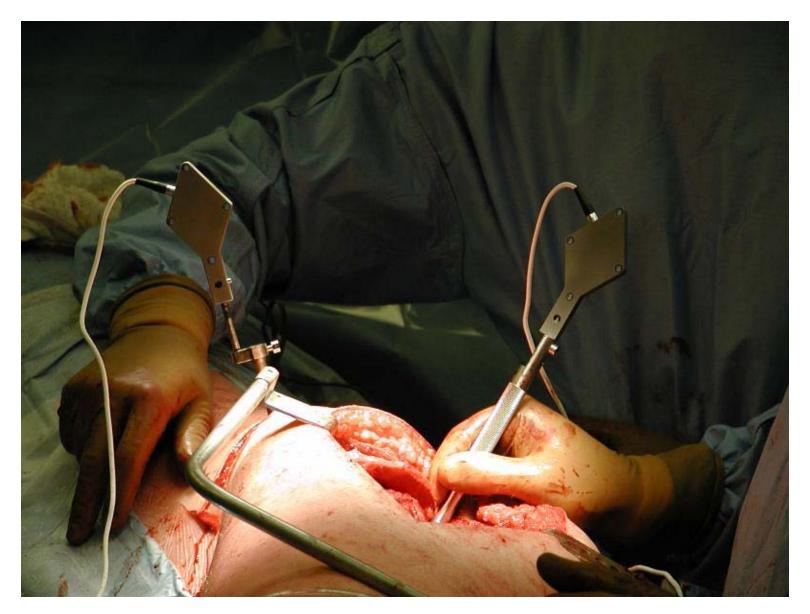

Landmarks: RoboSoccer

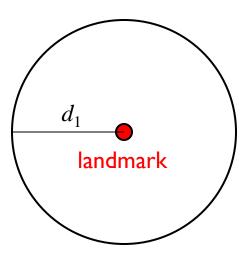

Landmarks: Retroreflector

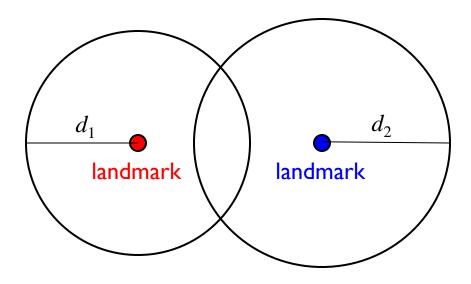

Landmarks: Active Light

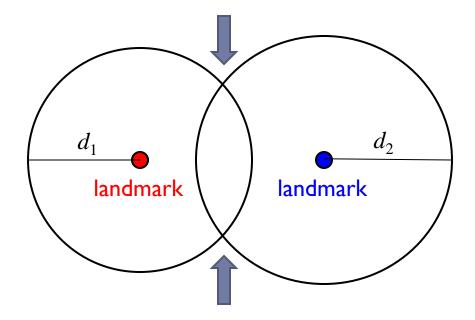

- uses distance measurements to two or more landmarks
- suppose a robot measures the distance d_1 to a landmark
 - the robot can be anywhere on a circle of radius d₁ around the landmark

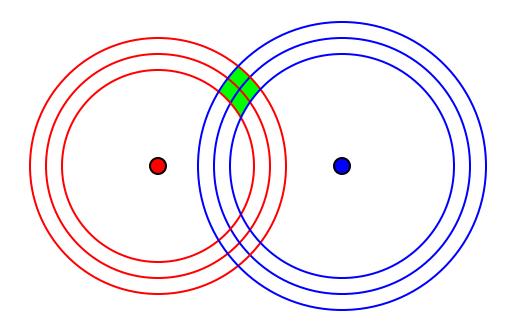

- without moving, suppose the robot measures the distance d₂ to a second landmark
 - the robot can be anywhere on a circle of radius d₂ around the second landmark

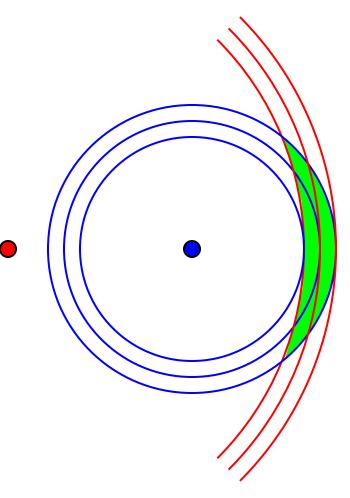

- the robot must be located at one of the two intersection points of the circles
 - tie can be broken if other information is known

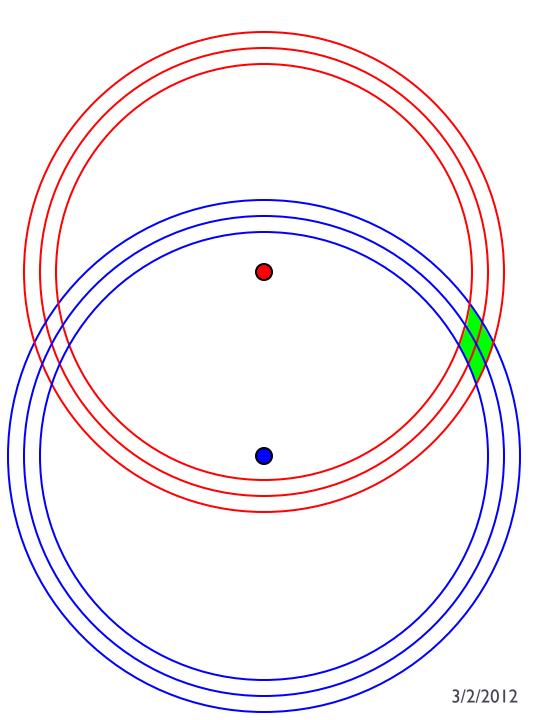

if the distance measurements are noisy then there will be some uncertainty in the location of the robot

- notice that the uncertainty changes depending on where the robot is relative to the landmarks
- uncertainty grows quickly if the robot is in line with the landmarks

- uncertainty grows as the robot moves farther away from the landmarks
 - but not as dramatically as the previously slide

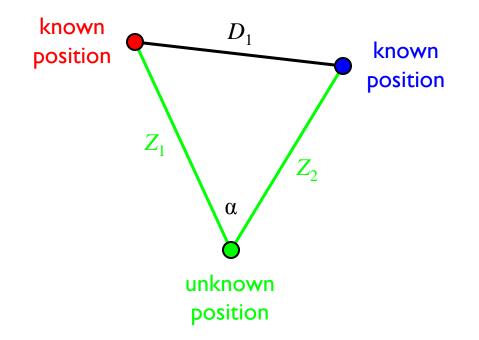

Triangulation

- triangulation uses angular information to infer position
 - http://longhamscouts.org.uk/content/view/52/38/

Triangulation

- in robotics the problem often appears as something like:
 - suppose the robot has a (calibrated) camera that detects two landmarks (with known location)
 - > then we can determine the angular separation, or relative bearing, α between the two landmarks

Triangulation

- the unknown position must lie somewhere on a circle arc
 - Euclid proved that any point on the shown circular arc forms an inscribed triangle with angle α
 - we need at least one more beacon to estimate the robot's location
