## Day 28

Path Planning in Discrete Sampled Space

## Spatial Decomposition

- represent space itself, rather than the objects in it, using discrete samples
- many ways to perform sampling, but the simplest is to use a grid

$\square$ free space
$\square$ occupied

## Uniform Spatial Sampling

- very general representation
grid locations can represent anything
- if something moves then the representation does not change dramatically
- limited by grid resolution
- large cell size gives a coarse representation
> small cell size is storage intensive
- football pitch at $\mathrm{Icm}^{2}$ resolution
$\square 105 \mathrm{~m} \times 68 \mathrm{~m} \times 100 \times 100=71,400,000$ cells
- 3D is much worse

## Recursive Hierarchical Representations

- storage space can be conserved by observing that free space cells and occupied cells tend to cluster
- group the clusters into larger cells
- quadtree
- recursively subdivide space into 4 equal-sized cells until every cell is either uniformly free or uniformly occupied
- or some threshold resolution is reached

## Quadtree Decomposition

$\square$ free space
$\square$ occupied

## Quadtree Decomposition

$\square$ free space
$\square$ occupied

## Quadtree Decomposition

$\square$ free space
$\square$ occupied

## Quadtree Decomposition

$\square$ free space
$\square$ occupied

## Quadtree Decomposition

$\square$ free space
$\square$ occupied

## Quadtree Decomposition

- worst case performance
- same as uniform subdivision
- if most of the space is occupied or freespace then the representation is compact
- generalizes to N dimensions
- representation changes dramatically if objects move even a small amount

## Connectivity in Discrete Sampled Space

- a path on a discrete grid is a sequence of moves between connected cells
- for a square tiling there are two possible definitions of connectivity

4-connectivity

8-connectivity

## 4-Connectivity

- on a 4-connected tiling the distance between two cells is called the taxicab distance, rectilinear distance, $L_{1}$ distance, $L_{1}$ norm, city block distance, or Manhattan distance

|  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |

## Wave-Front Planner

- the wave-front planner finds a path between a start and goal point in spaces represented as a grid where
- free space is labeled with a 0
- obstacles are labeled with a I
p the goal is labeled with a 2
- the start is known

## Wave-Front Planner

- advantage:
vill find a shortest path (in terms of connectivity) between start and goal if a path exists
- generalizes to higher dimensions
- disadvantages:
- path often runs adjacent to obstacles
- planner searches the entire space with radius R around the goal (where R is the distance between the start and goal)
p paths restricted by grid connectivity are longer than necessary

## Wave-Front Planner

- paths restricted by grid connectivity are longer than necessary
- Manhattan distance $=9$
- straight line distance $=\operatorname{sqrt}(16+25)=6.403 . .$.

|  |  |  |  |  |  |  |  |

## Greedy Best-First Search

- to avoid searching in all possible directions we might consider searching first in a direction towards the goal
- idea
b use an estimate (called the heuristic) of how far a cell is from the goal
- consider the cell whose heuristic distance is the smallest first

possible path with heuristic distance $=$ Euclidean distance

## Greedy Best-First Search

- produces expensive paths when there are concave obstacles

- $\mathrm{A}^{*}$ is a common algorithm in game Al programming and robotics
- first described in 1968
- http://theory.stanford.edu/~amitp/GameProgramming/
- $A^{*}$ is the foundation for Theta*
- Daniel, Nash, Koenig. Theta*:Any-Angle Planning on Grids, Journal of Artificial Intelligence Research, 39, 2010.
- path planning on a grid where paths are allowed to pass through cells at any angle (not just using 4- or 8-connectivity)

A* combines two pieces of information
$g(n)$ : the cost of the path from the starting point to $n$

- $h(n)$ : the heuristic cost of the path from $n$ to the goal
- considers the cell $n$ with the lowest cost

$$
f(n)=g(n)+h(n)
$$

first

- compromise between Dijkstra's algorithm and greedy bestfirst search
- the heuristic distance function $\mathrm{h}(\mathrm{n})$ affects how the algorithm performs the search
- $h(n)=0$
- equivalent to Dijkstra's algorithm
- $\mathrm{h}(\mathrm{n})<=$ true cost of moving from n to the goal
- guaranteed to find a shortest path
- the smaller $\mathrm{h}(\mathrm{n})$ the more it expands the search to cells closer to the start
- $h(n)=$ true cost of moving from $n$ to the goal
- will find a best path with the minimal amount of searching
- $h(n)>$ true cost of moving from $n$ to the goal some of the time
- not guaranteed to find a shortest path but might find a path in a shorter amount of time
> $h(n) \gg$ true cost of moving from $n$ to the goal
b behaves like greedy best-first search
- $h(n)<=$ true cost of moving from $n$ to the goal
- $h(n)>$ true cost of moving from $n$ to the goal

## Potential Functions

- in continuous space potential functions can be used for path planning
- a potential function is a differentiable real-valued function $U$

$$
U: \mathrm{R}^{m} \rightarrow \mathrm{R}
$$

- i.e., $U$ assigns a scalar real value to every point in space
- potential functions you might know
- gravitational potential
- electrostatic potential

## Goal Potential

- the goal potential should be an attractive potential
b small near the goal
- large far from the goal
- monotonically increasing
- nice too if it is continuously differentiable

## Goal Potential

- consider the quadratic potential

$$
U_{\text {atract }}=\alpha\left\|q-q_{\text {goal }}\right\|^{2}
$$

## Goal Potential

- "rolling towards the goal" can be accomplished using gradient descent

$$
\begin{aligned}
F & =\nabla U_{\text {attract }} \\
& =\left[\begin{array}{c}
\partial U / \partial x \\
\partial U / \partial y
\end{array}\right] \\
& =\alpha\left(q-q_{\text {goal }}\right)
\end{aligned}
$$

gradient descent

- starting at initial configuration, take a small step in the direction opposite to the gradient $F$ until $|F|=0$

## Goal Potential

- notice that the wave-front planner basically works this way
- it defines a potential where there is only one minimum
- the minimum is located at the goal
- it then uses gradient descent to move towards the goal
