Formality of Java Programming Part 2 Steven Castellucci

Division of Responsibilities

- Often programming in teams or large groups
- Need efficient technique to...
 - Describe who does what
 - What classes/methods are needed
 - What methods will take as arguments
 - What methods will return as results
 - What methods will throw if there is an error

The Client-Implementer View

- The **client** develops the main class
 - Understands the big picture, the purpose of the application
 - Knows what each component does but not how it does it
- The implementer develops a component
 - Focuses only on the inner details of one component
- Client and Implementer share info on a need-to-know basis

The Client-Implementer View

CLIENT

 The "interface" is the application programming interface (API)

Contracts

- Guarantee between client and implementer
- Precondition
 - What the client must satisfy
- Postcondition
 - What the implementer must deliver
- Liability
 - Pre. is satisfied and post. is satisfied \rightarrow Good
 - $^{\circ}$ Pre. is satisfied and post. is not satisfied \rightarrow Implementer at fault
 - Pre. is not satisfied \rightarrow Client at fault
 - If no precondition stated, then client need not satisfy anything

Contracts in Java

- Methods in the Java specify contracts as follows:
 - Precondition is always true unless stated otherwise
 - Postcondition is specified under Returns and Throws
- Example:

```
double squareRoot(double x)
Returns the square root of the given argument.
Parameters:
    x - an argument.
Returns:
    the positive square root of x.
Throws:
    an exception if x < 0.</pre>
```

Testing

- Imperative to test all classes for correctness
- Compare calculated output with expected output
 - Identical result \rightarrow test passed
 - Different result \rightarrow test failed
- Testing requires multiple test cases to ensure correct operation under various condition with various inputs
- Example: Test kilometresToMiles method

Testing (Implemented Code)

public class DistanceUtility

ł

}

public static final double MI_PER_KM = 0.621371;

private DistanceUtility() {}

public static double kilometresToMiles(double km)
{
 return km * MI PER KM;

Testing (Testing Class)

```
public class DistUtilTester
  public static void main(String[] args)
    double input = 2;
    double expected = 1.24274238; // used calculator as oracle
    double actual = DistanceUtility.kilometresToMiles(input);
    double epsilon = 0.000001;
    if (Math.abs(actual - expected) < epsilon)
      System.out.println("passed");
    else
      System.out.println("failed");
```

Testing (JUnit in Eclipse)

Choosing Test Cases

- Test cases should represent valid and invalid inputs to test correctness and robustness
- Boundary cases often described by
 - If-statements
 - Loop conditions
- But what if you don't have access to the code?

Black-Box Testing

- Testing a program, class, or module without having access to its code
- Choose test cases based solely on contract information provided by API
