

Aggregation and Composition

[notes Chapter 4]

Aggregation and Composition

- ▶ the terms aggregation and composition are used to describe a relationship between objects
- ▶ both terms describe the *has-a* relationship
 - ▶ the university has-a collection of departments
 - ▶ each department has-a collection of professors

Aggregation and Composition

- ▶ composition implies ownership
 - ▶ if the university disappears then all of its departments disappear
 - ▶ a university is a *composition* of departments
- ▶ aggregation does not imply ownership
 - ▶ if a department disappears then the professors do not disappear
 - ▶ a department is an *aggregation* of professors

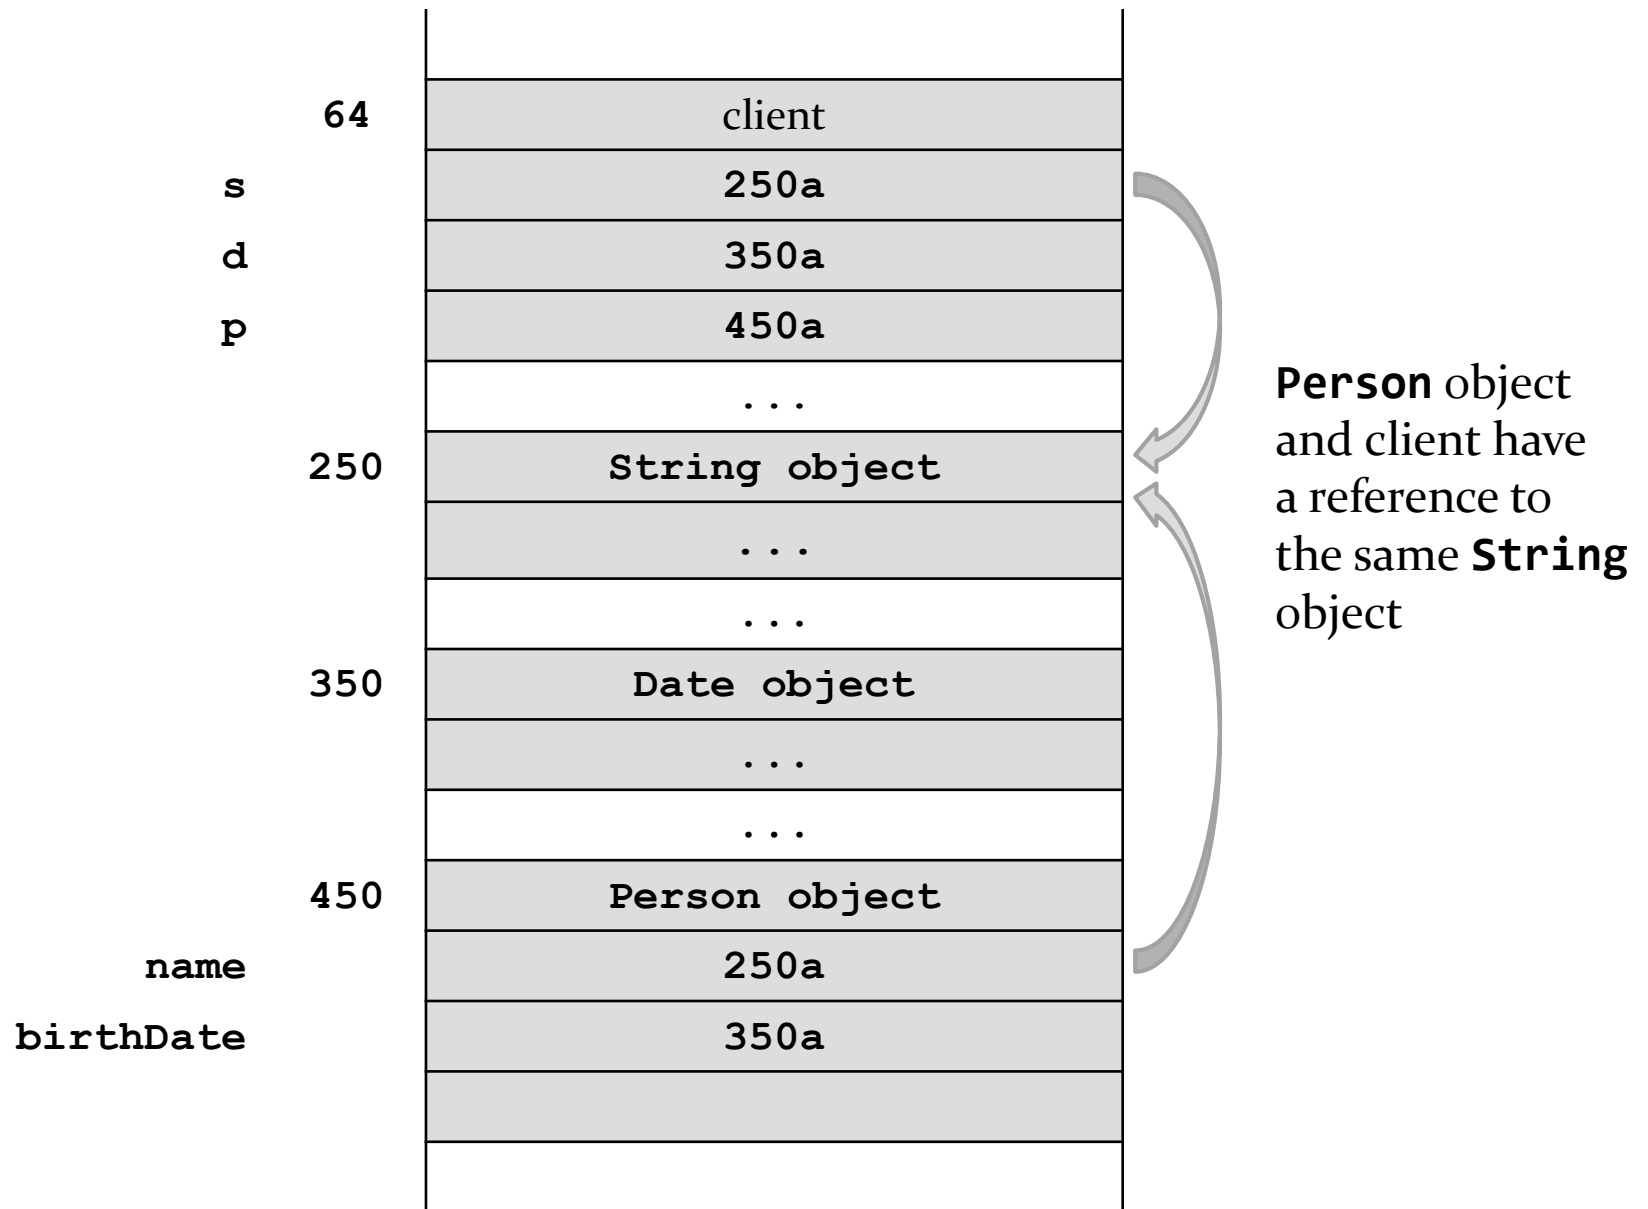

Aggregation

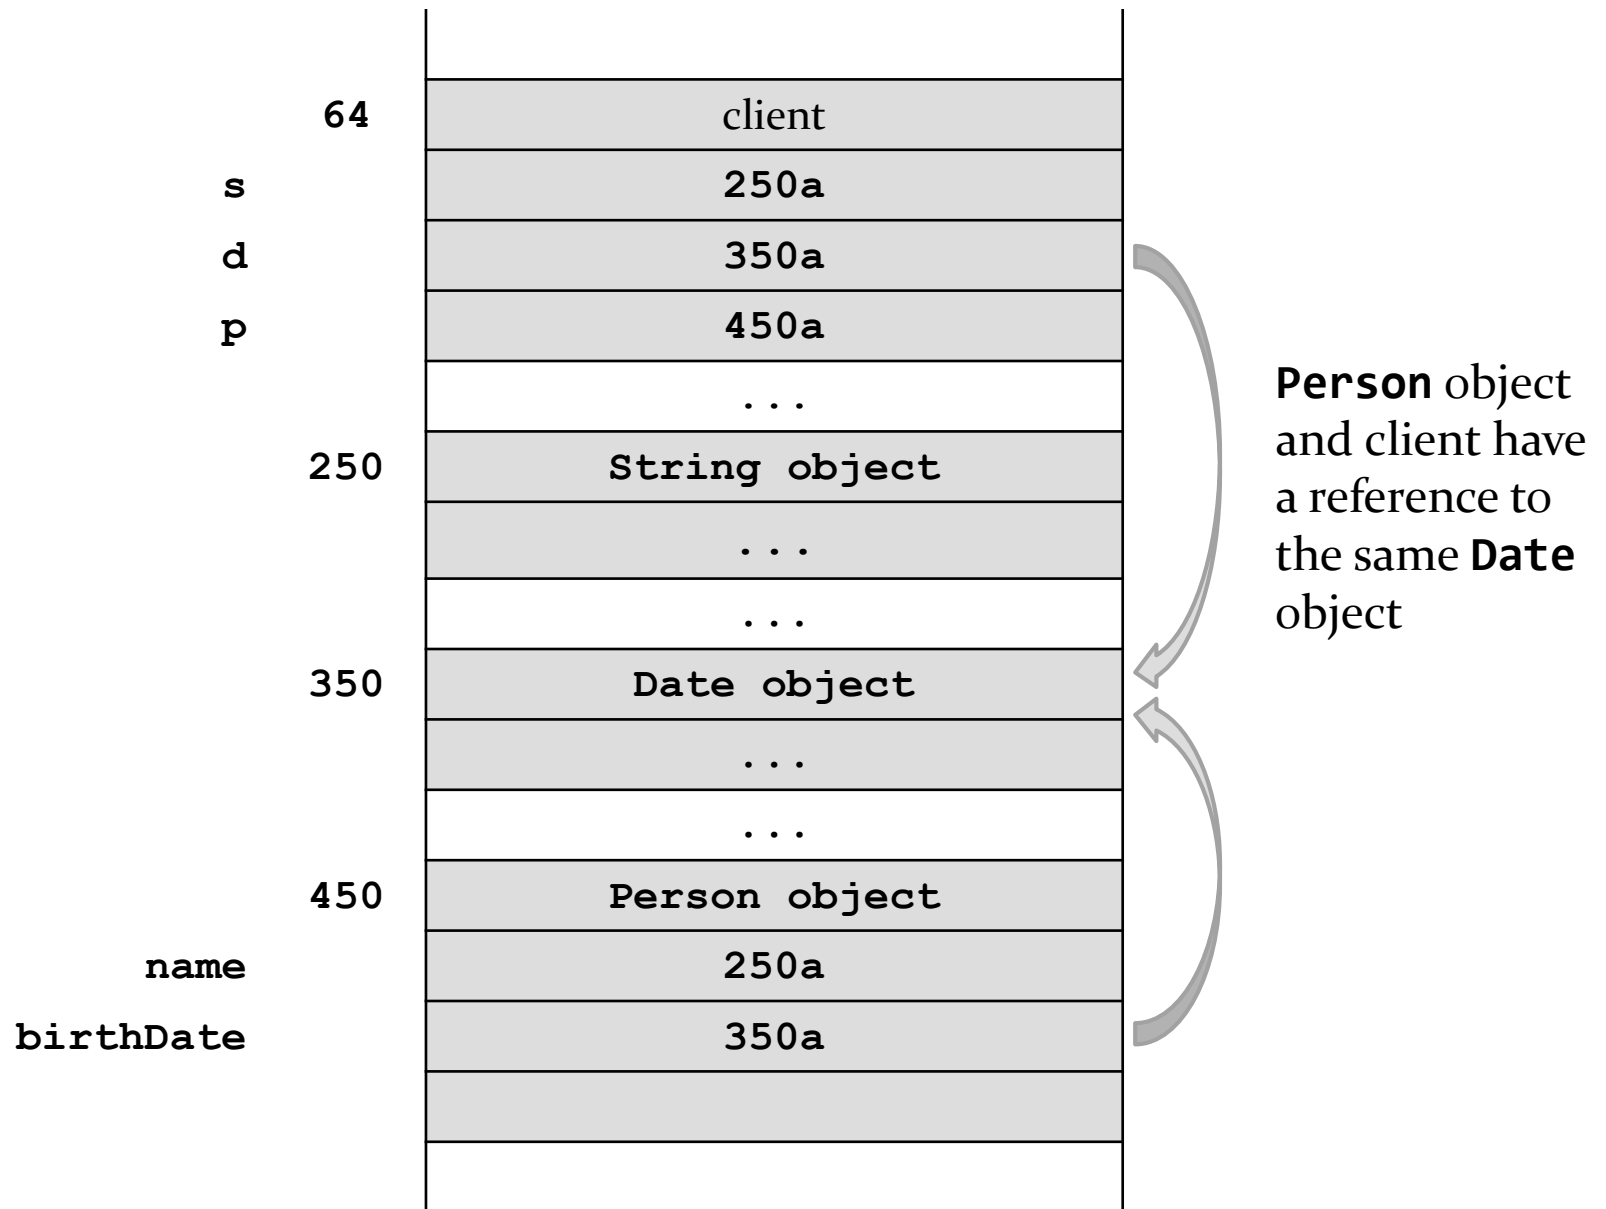

- ▶ suppose a **Person** has a name and a date of birth

```
public class Person {  
    private String name;  
    private Date birthDate;  
  
    public Person(String name, Date birthDate) {  
        this.name = name;  
        this.birthDate = birthDate;  
    }  
  
    public Date getBirthDate() {  
        return this.birthDate;  
    }  
}
```

-
- ▶ the **Person** example uses aggregation
 - ▶ notice that the constructor does not make a new copy of the name and birth date objects passed to it
 - ▶ the name and birth date objects are shared with the client
 - ▶ both the client and the **Person** instance are holding references to the same name and birth date

```
// client code somewhere
String s = "Billy Bob";
Date d = new Date(91, 2, 26); // March 26, 1991
Person p = new Person(s, d);
```

-
- ▶ what happens when the client modifies the **Date** instance?

```
// client code somewhere
String s = "Billy Bob";
Date d = new Date(90, 2, 26); // March 26, 1990
Person p = new Person(s, d);

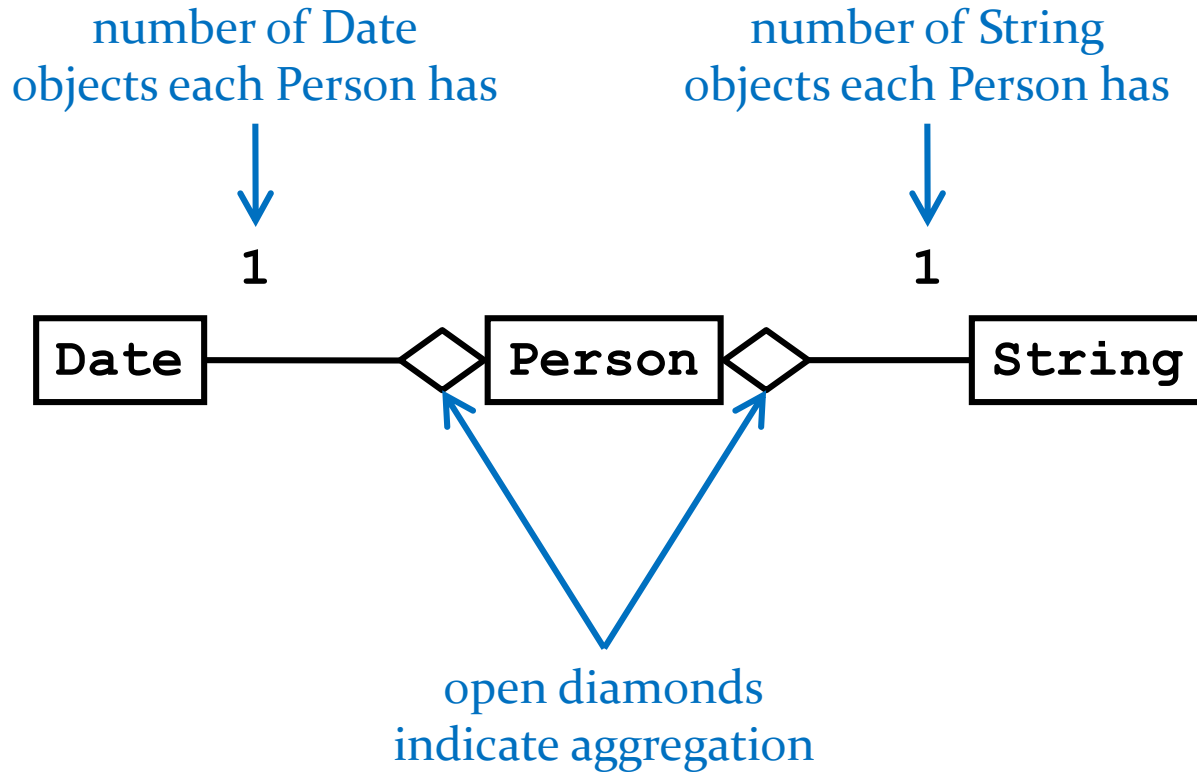

d.setYear(95); // November 3, 1995
d.setMonth(10);
d.setDate(3);
System.out.println( p.getBirthDate() );
```

- ▶ prints **Fri Nov 03 00:00:00 EST 1995**

-
- ▶ because the **Date** instance is shared by the client and the **Person** instance:
 - ▶ the client can modify the date using **d** and the **Person** instance **p** sees a modified **birthDate**
 - ▶ the **Person** instance **p** can modify the date using **birthDate** and the client sees a modified date **d**

-
- ▶ note that even though the **String** instance is shared by the client and the **Person** instance **p**, neither the client nor **p** can modify the **String**
 - ▶ immutable objects make great building blocks for other objects
 - ▶ they can be shared freely without worrying about their state

UML Class Diagram for Aggregation

Another Aggregation Example

- ▶ the **Ball** class from Lab 3 could be implemented using aggregation

```
public class Ball {  
  
    /**  
     * The current position of the ball.  
     */  
    private Point2 position;  
  
    /**  
     * The current velocity of the ball.  
     */  
    private Vector2 velocity;  
  
    /**  
     * Gravitational acceleration vector.  
     */  
    private static final Vector2 G = new Vector2(0.0, -9.81);  
}
```

```
/**
 * Initialize the ball so that its position and velocity are
 * equal to the given position and velocity.
 *
 * @param position
 *         the position of the ball
 * @param velocity
 *         the velocity of the ball
 */
public Ball(Point2 position, Vector2 velocity) {
    this.position = position;
    this.velocity = velocity;
}
```

```
/**
 * Return the position of the ball.
 *
 * @return the position of the ball
 */
public Point2 getPosition() {
    return this.position;
}
```

```
/**
 * Return the velocity of the ball.
 *
 * @return the velocity of the ball
 */
public Vector2 getVelocity() {
    return this.velocity;
}
```

```
/**
 * Set the position of the ball to the given position.
 *
 * @param position
 *         the new position of the ball
 */
public void setPosition(Point2 position) {
    this.position = position;
}
```

```
/**
 * Set the velocity of the ball to the given velocity.
 *
 * @param velocity
 *         the new velocity of the ball
 */
public void setVelocity(Vector2 velocity) {
    this.velocity = velocity;
}
```

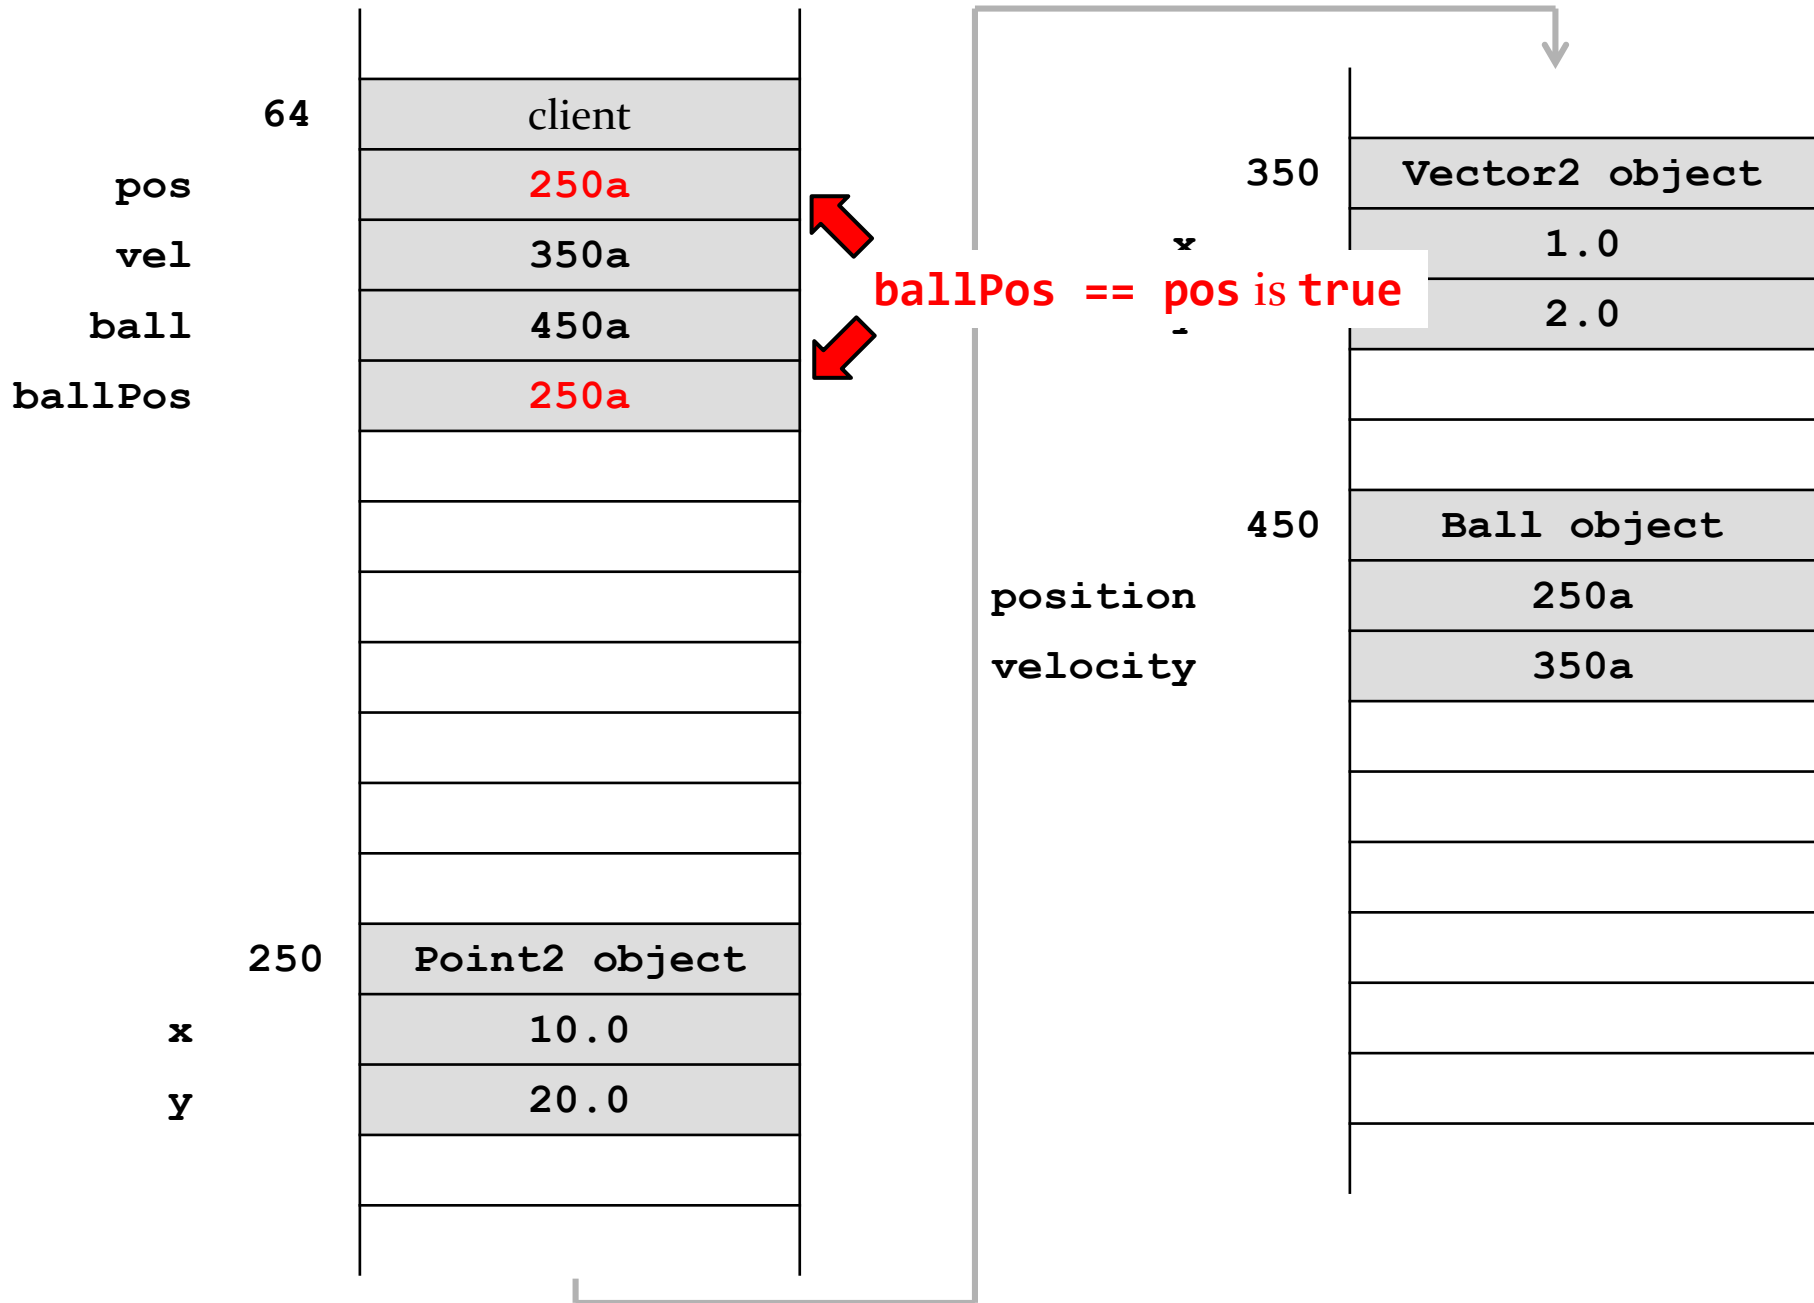

Ball as an aggregation

- ▶ implementing **Ball** is very easy
- ▶ fields
 - ▶ are references to existing objects provided by the client
- ▶ accessors
 - ▶ give clients a reference to the aggregated **Point2** and **Vector2** objects
- ▶ mutators
 - ▶ set fields to existing object references provided by the client
- ▶ we say that the **Ball** fields are *aliases*

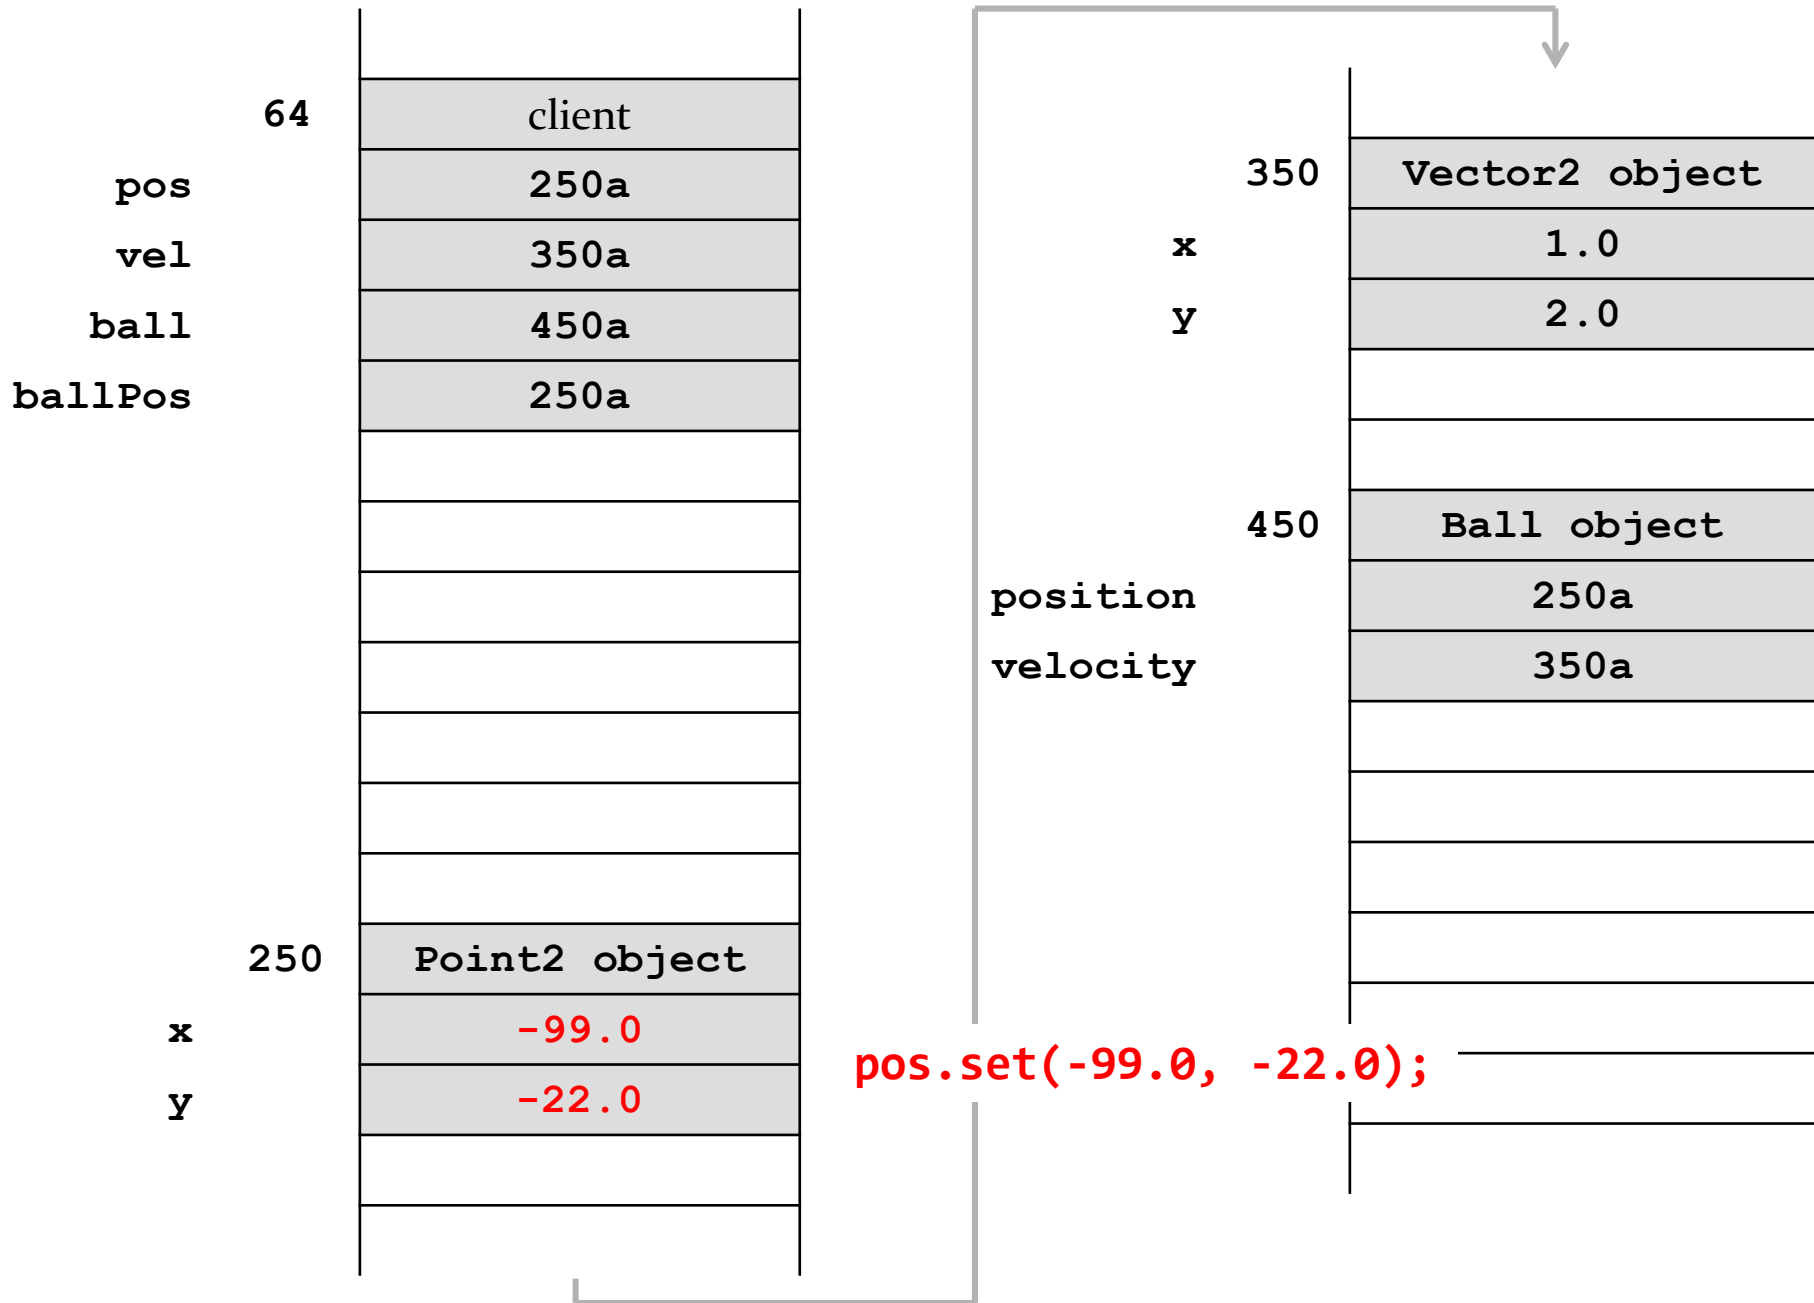

```
public static void main(String[] args) {  
    Point2 pos = new Point2(10.0, 20.0);  
    Vector2 vel = new Vector2(1.0, 2.0);  
    Ball ball = new Ball(pos, vel);  
}
```

```
public static void main(String[] args) {  
    Point2 pos = new Point2(10.0, 20.0);  
    Vector2 vel = new Vector2(1.0, 2.0);  
    Ball ball = new Ball(pos, vel);  
  
    // does ball and client share the same objects?  
    Point2 ballPos = ball.getPosition();  
    System.out.println("same Point2 object?: " + (ballPos == pos));  
}
```

```
public static void main(String[] args) {  
    Point2 pos = new Point2(10.0, 20.0);  
    Vector2 vel = new Vector2(1.0, 2.0);  
    Ball ball = new Ball(pos, vel);  
  
    // does ball and client share the same objects?  
    Point2 ballPos = ball.getPosition();  
    System.out.println("same Point2 object?: " + (ballPos == pos));  
  
    // client changes pos  
    pos.set(-99.0, -22.0);  
    System.out.println("ball position: " + ballPos);  
}
```

Ball as aggregation

- ▶ if a client gets a reference to the position or velocity of the ball, then the client can change these quantities *without asking the ball*
- ▶ this is not a flaw of aggregation
 - ▶ it's just the consequence of choosing to use aggregation

Composition

Composition

- ▶ recall that an object of type **X** that is composed of an object of type **Y** means
 - ▶ **X** has-a **Y** object *and*
 - ▶ **X** owns the **Y** object
- ▶ in other words

the **X** object has exclusive access to its **Y** object

Composition

the **X** object has exclusive access to its **Y** object

- ▶ this means that the **X** object will generally not share references to its **Y** object with clients
 - ▶ constructors will create new **Y** objects
 - ▶ accessors will return references to new **Y** objects
 - ▶ mutators will store references to new **Y** objects
- ▶ the “new **Y** objects” are called *defensive copies*

Composition & the Default Constructor

the **X** object has exclusive access to its **Y** object

- ▶ if a default constructor is defined it must create a suitable **Y** object

```
public X()  
{  
    // create a suitable Y; for example  
    this.y = new Y( /* suitable arguments */ );  
}
```

defensive copy

Composition & Other Constructors

the **X** object has exclusive access to its **Y** object

- ▶ a constructor that has a **Y** parameter must first deep copy and then validate the **Y** object

```
public X(Y y)
{
    // create a copy of y
    Y copyY = new Y(y); } defensive copy
    // validate; will throw an exception if copyY is invalid
    this.checkY(copyY);
    this.y = copyY;
}
```

Composition and Other Constructors

- ▶ why is the deep copy required?

the **X** object has exclusive access to its **Y** object

- ▶ if the constructor does this

```
// don't do this for composition
public X(Y y) {
    this.y = y;
}
```

then the client and the **X** object will share the same **Y** object

- ▶ this is called a privacy leak

► Worksheet Question 1

Composition & Copy Constructor

the **X** object has exclusive access to its **Y** object

- ▶ if a copy constructor is defined it must create a new **Y** that is a deep copy of the other **X** object's **Y** object

```
public X(X other)
{
    // create a new Y that is a copy of other.y
    this.y = new Y(other.getY());
}
```

defensive copy

Composition & Copy Constructor

- ▶ what happens if the **X** copy constructor does not make a deep copy of the other **X** object's **Y** object?

```
// don't do this
public X(X other)
{
    this.y = other.y;
}
```

- ▶ every **X** object created with the copy constructor ends up sharing its **Y** object
 - ▶ if one **X** modifies its **Y** object, all **X** objects will end up with a modified **Y** object
 - ▶ this is called a privacy leak

► Worksheet Question 2

Composition and Accessors

the **X** object has exclusive access to its **Y** object

- ▶ never return a reference to a field; always return a deep copy

```
public Y getY()  
{  
    return new Y(this.y);  
}
```

} defensive copy

Composition and Accessors

- ▶ why is the deep copy required?

the **X** object has exclusive access to its **Y** object

- ▶ if the accessor does this

```
// don't do this for composition
public Y getY() {
    return this.y;
}
```

then the client and the **X** object will share the same **Y** object

- ▶ this is called a privacy leak

► Worksheet Question 3

Composition and Mutators

the **X** object has exclusive access to its **Y** object

- ▶ if **X** has a method that sets its **Y** object to a client-provided **Y** object then the method must make a deep copy of the client-provided **Y** object and validate it

```
public void setY(Y y)
{
    Y copyY = new Y(y); } defensive copy
    // validate; will throw an exception if copyY is invalid
    this.checkY(copyY);
    this.y = copyY;
}
```

Composition and Mutators

- ▶ why is the deep copy required?

the **X** object has exclusive access to its **Y** object

- ▶ if the mutator does this

```
// don't do this for composition
public void setY(Y y) {
    this.y = y;
}
```

then the client and the **X** object will share the same **Y** object

- ▶ this is called a privacy leak

► Worksheet Question 4

Price of Defensive Copying

- ▶ defensive copies are required when using composition, but the price of defensive copying is time and memory needed to create and garbage collect defensive copies of objects
- ▶ recall the **Ball** program from Lab 3
 - ▶ if you used aggregation then moving the ball could be done without making any defensive copies

```

/**
 * Moves the ball from its current position using its current
 * velocity accounting for the force of gravity. See the Lab 3
 * document for a description of how to compute the new position
 * and velocity of the ball.
 *
 * @param dt
 *         the time period over which the ball has moved
 * @return the new position of the ball
 */
public Point2 move(double dt) {
    Vector2 dp1 = Lab3Util.multiply(dt, this.velocity);
    Vector2 dp2 = Lab3Util.multiply(0.5 * dt * dt, Ball.G);
    Vector2 dp = Lab3Util.add(dp1, dp2);
    this.position = Lab3Util.add(this.position, dp);
    Vector2 dv = Lab3Util.multiply(dt, Ball.G);
    this.velocity.add(dv);
    return this.position;
}

```

Price of Defensive Copying

- ▶ if we use composition to implement **Ball** then `move` must return a defensive copy of **`this.position`**
- ▶ this doesn't seem like such a big deal until you realize that the **BouncingBall** program causes the ball to move many times each second

Composition (Part 2)

Class Invariants

- ▶ class invariant
 - ▶ some property of the state of the object that is established by a constructor and maintained between calls to public methods
 - ▶ in other words:
 - ▶ the constructor ensures that the class invariant holds when the constructor is finished running
 - the invariant does not necessarily hold while the constructor is running
 - ▶ every public method ensures that the class invariant holds when the method is finished running
 - the invariant does not necessarily hold while the method is running

Period Class

- ▶ adapted from Effective Java by Joshua Bloch
 - ▶ available online at <http://www.informit.com/articles/article.aspx?p=31551&seqNum=2>
- ▶ we want to implement a class that represents a period of time
 - ▶ a period has a start time and an end time
 - ▶ end time is always after the start time (this is the class invariant)

Period Class

- ▶ we want to implement a class that represents a period of time
 - ▶ has-a **Date** representing the start of the time period
 - ▶ has-a **Date** representing the end of the time period
 - ▶ class invariant: start of time period is always prior to the end of the time period

Period Class

Period is a composition
of two **Date** objects

```
import java.util.Date;

public class Period {
    private Date start;
    private Date end;

    /**
     * Initialize the period to the given start and end dates.
     *
     * @param start beginning of the period
     * @param end end of the period; must not precede start
     * @throws IllegalArgumentException if start is after end
     */
    public Period(Date start, Date end) {
        if (start.compareTo(end) > 0) {
            throw new IllegalArgumentException("start after end");
        }
        this.start = start;
        this.end = end;
    }
}
```

► Worksheet Question 5

```
/**
 * Initializes a period by copying another period.
 *
 * @param other the time period to copy
 */
public Period(Period other) {
    this.start = other.start;
    this.end = other.end;
}
```

► Worksheet Question 6

```
/**
 * Returns the starting date of the period.
 *
 * @return the starting date of the period
 */
public Date getStart() {
    return this.start;
}
```

```
/**
 * Returns the ending date of the period.
 *
 * @return the ending date of the period
 */
public Date getEnd() {
    return this.end;
}
```

► Worksheet Question 7

```
/**
 * Sets the starting date of the period.
 *
 * @param newStart the new starting date of the period
 * @return true if the new starting date is earlier than the
 *         current end date; false otherwise
 */
public boolean setStart(Date newStart) {
    boolean ok = false;
    if (newStart.compareTo(this.end) < 0) {
        this.start = newStart;
        ok = true;
    }
    return ok;
}
```

► Worksheet Question 8

Privacy Leaks

- ▶ a privacy leak occurs when a class exposes a reference to a non-public field (that is not a primitive or immutable)
- ▶ given a class **X** that is a composition of a **Y**

```
public class X {  
    private Y y;  
    // ...  
}
```

these are all examples of privacy leaks

```
public X(Y y) {  
    this.y = y;  
}
```

```
public X(X other) {  
    this.y = other.y;  
}
```

```
public Y getY() {  
    return this.y;  
}
```

```
public void setY(Y y) {  
    this.y = y;  
}
```

Consequences of Privacy Leaks

- ▶ a privacy leak allows some other object to control the state of the object that leaked the field
 - ▶ the object state can become inconsistent
 - ▶ example: if a **CreditCard** exposes a reference to its expiry **Date** then a client could set the expiry date to before the issue date

Consequences of Privacy Leaks

- ▶ a privacy leak allows some other object to control the state of the object that leaked the field
 - ▶ it becomes impossible to guarantee class invariants
 - ▶ example: if a **Period** exposes a reference to one of its **Date** objects then the end of the period could be set to before the start of the period

Consequences of Privacy Leaks

- ▶ a privacy leak allows some other object to control the state of the object that leaked the field
 - ▶ composition becomes broken because the object no longer owns its attribute
 - ▶ when an object “dies” its parts may not die with it

Recipe for Immutability

- ▶ the recipe for immutability in Java is described by Joshua Bloch in the book *Effective Java**
- 1. Do not provide any methods that can alter the state of the object
- 2. Prevent the class from being extended revisit when we talk about inheritance
- 3. Make all fields **final**
- 4. Make all fields **private**
- 5. Prevent clients from obtaining a reference to any mutable fields

Immutability and Composition

- ▶ why is Item 5 of the Recipe for Immutability needed?

Collections as fields

Still Aggregation and Composition

Motivation

- ▶ often you will want to implement a class that has-a collection as a field
 - ▶ a university has-a collection of faculties and each faculty has-a collection of schools and departments
 - ▶ a molecule has-a collection of atoms
 - ▶ a person has-a collection of acquaintances
 - ▶ from the notes, a student has-a collection of GPAs and has-a collection of courses

What Does a Collection Hold?

- ▶ a collection holds references to instances
 - ▶ it does not hold the instances

```
ArrayList<Date> dates =  
    new ArrayList<Date>();
```

```
Date d1 = new Date();  
Date d2 = new Date();  
Date d3 = new Date();
```

```
dates.add(d1);  
dates.add(d2);  
dates.add(d3);
```

100

dates

d1

d2

d3

200

client invocation

200a

500a

600a

700a

...

ArrayList object

500a

600a

700a

► Worksheet Question 9

Student Class (from notes)

- ▶ a Student has-a string id
- ▶ a Student has-a collection of yearly GPAs
- ▶ a Student has-a collection of courses

Firework class

- ▶ see Lab 4
- ▶ a **Firework** has-a list of **Particles**
 - ▶ aggregation
- ▶ class invariant
 - ▶ list of particles is never null

```
public class Firework {  
  
    /**  
     * The particles for this firework.  
     */  
    private List<Particle> particles;  
  
    /**  
     * Initializes this firework to have zero particles.  
     */  
    public Firework() {  
        this.particles = new ArrayList<Particle>();  
    }  
}
```

Collections as fields

- ▶ when using a collection as a field of a class **X** you need to decide on ownership issues
 - ▶ does **X** own or share its collection?
 - ▶ if **X** owns the collection, does **X** own the objects held in the collection?

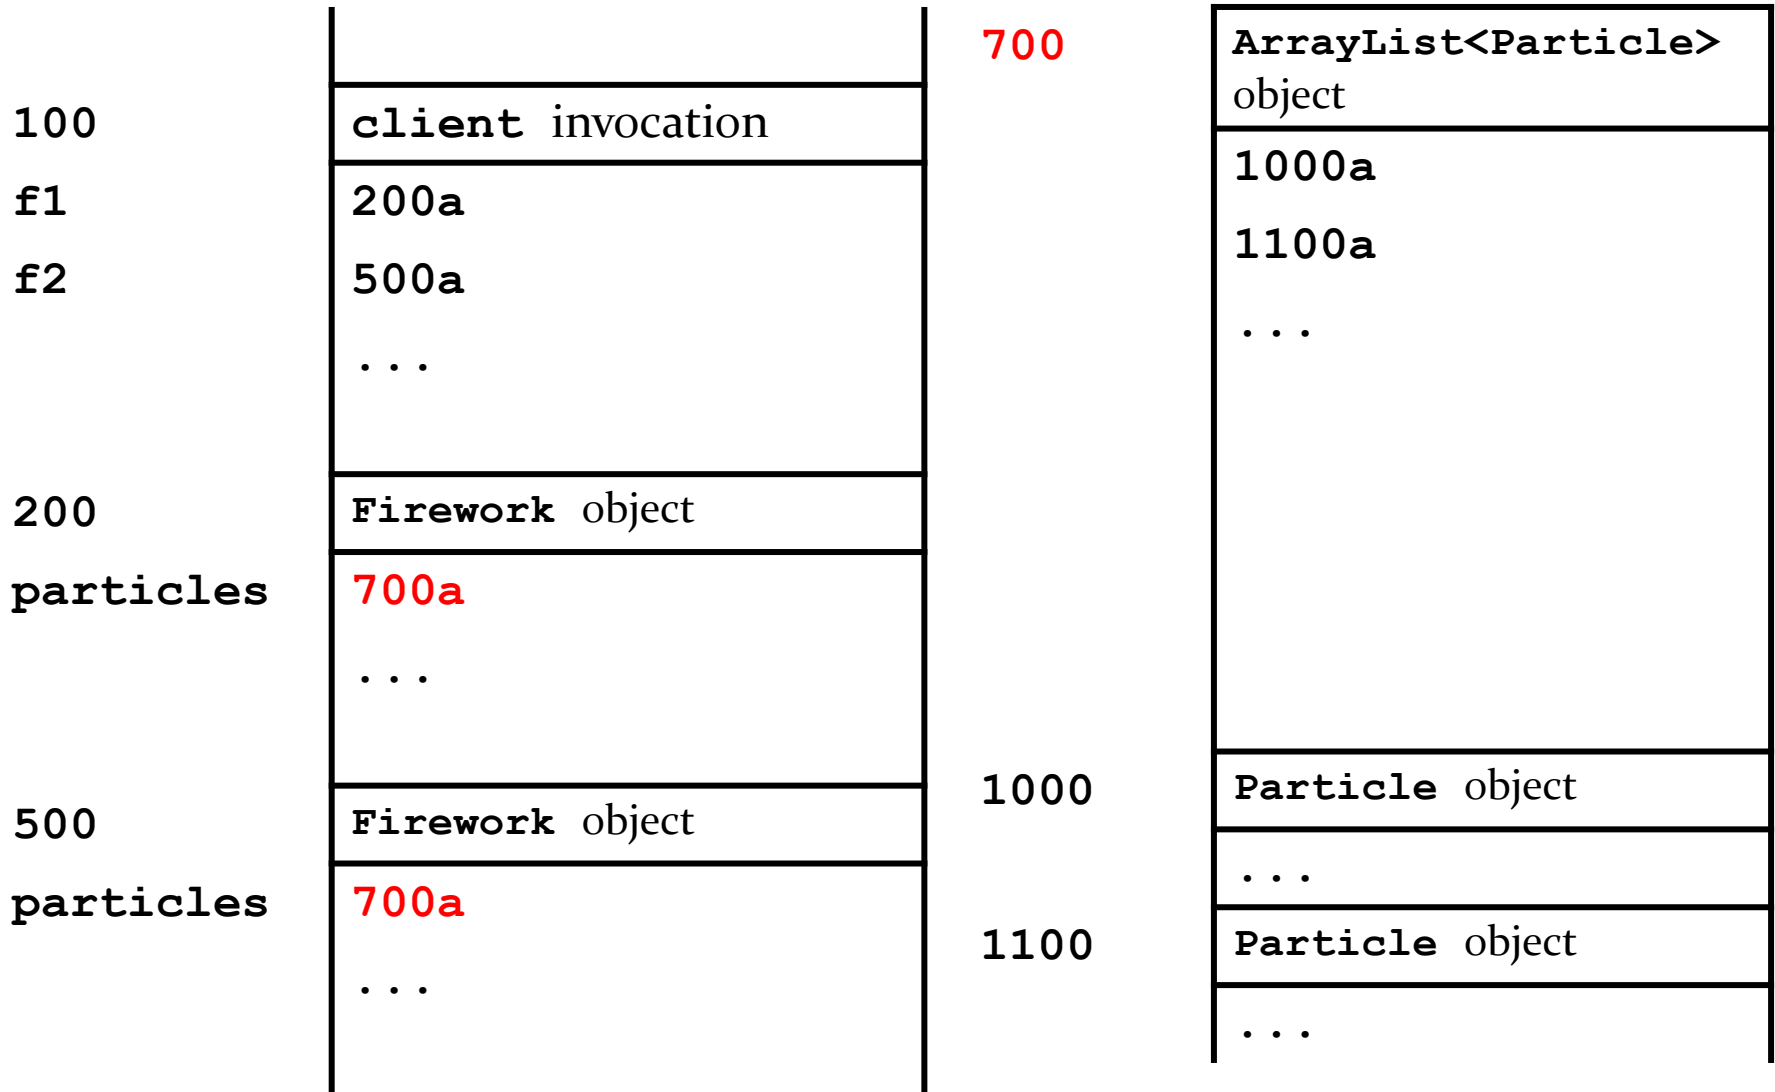

X Shares its Collection with other **X**s

- ▶ if **X** shares its collection with other **X** instances, then the copy constructor does not need to create a new collection
 - ▶ the copy constructor can simply assign its collection
 - ▶ [notes 5.3.3] refer to this as aliasing

```
/**
 * Initializes this firework so that its particles alias
 * the particles of another firework.
 *
 * @param other another firework
 */
public Firework(Firework other) {
    this.particles = other.particles;
}
```

alias: no new **List**
created

```
Firework f2 = new Firework(f1);
```

► Worksheet Question 10

X Owns its Collection: Shallow Copy

- ▶ if **X** owns its collection but not the objects in the collection then the copy constructor can perform a shallow copy of the collection
- ▶ a shallow copy of a collection means
 - ▶ **X** creates a new collection
 - ▶ the references in the collection are aliases for references in the other collection

X Owns its Collection: Shallow Copy

- ▶ the hard way to perform a shallow copy

```
// assume there is an ArrayList<Date> dates
ArrayList<Date> sCopy = new ArrayList<Date>();
for(Date d : dates)
{
    sCopy.add(d);
}
```

add does not create
new objects

shallow copy: new **List**
created but elements
are all aliases

X Owns its Collection: Shallow Copy

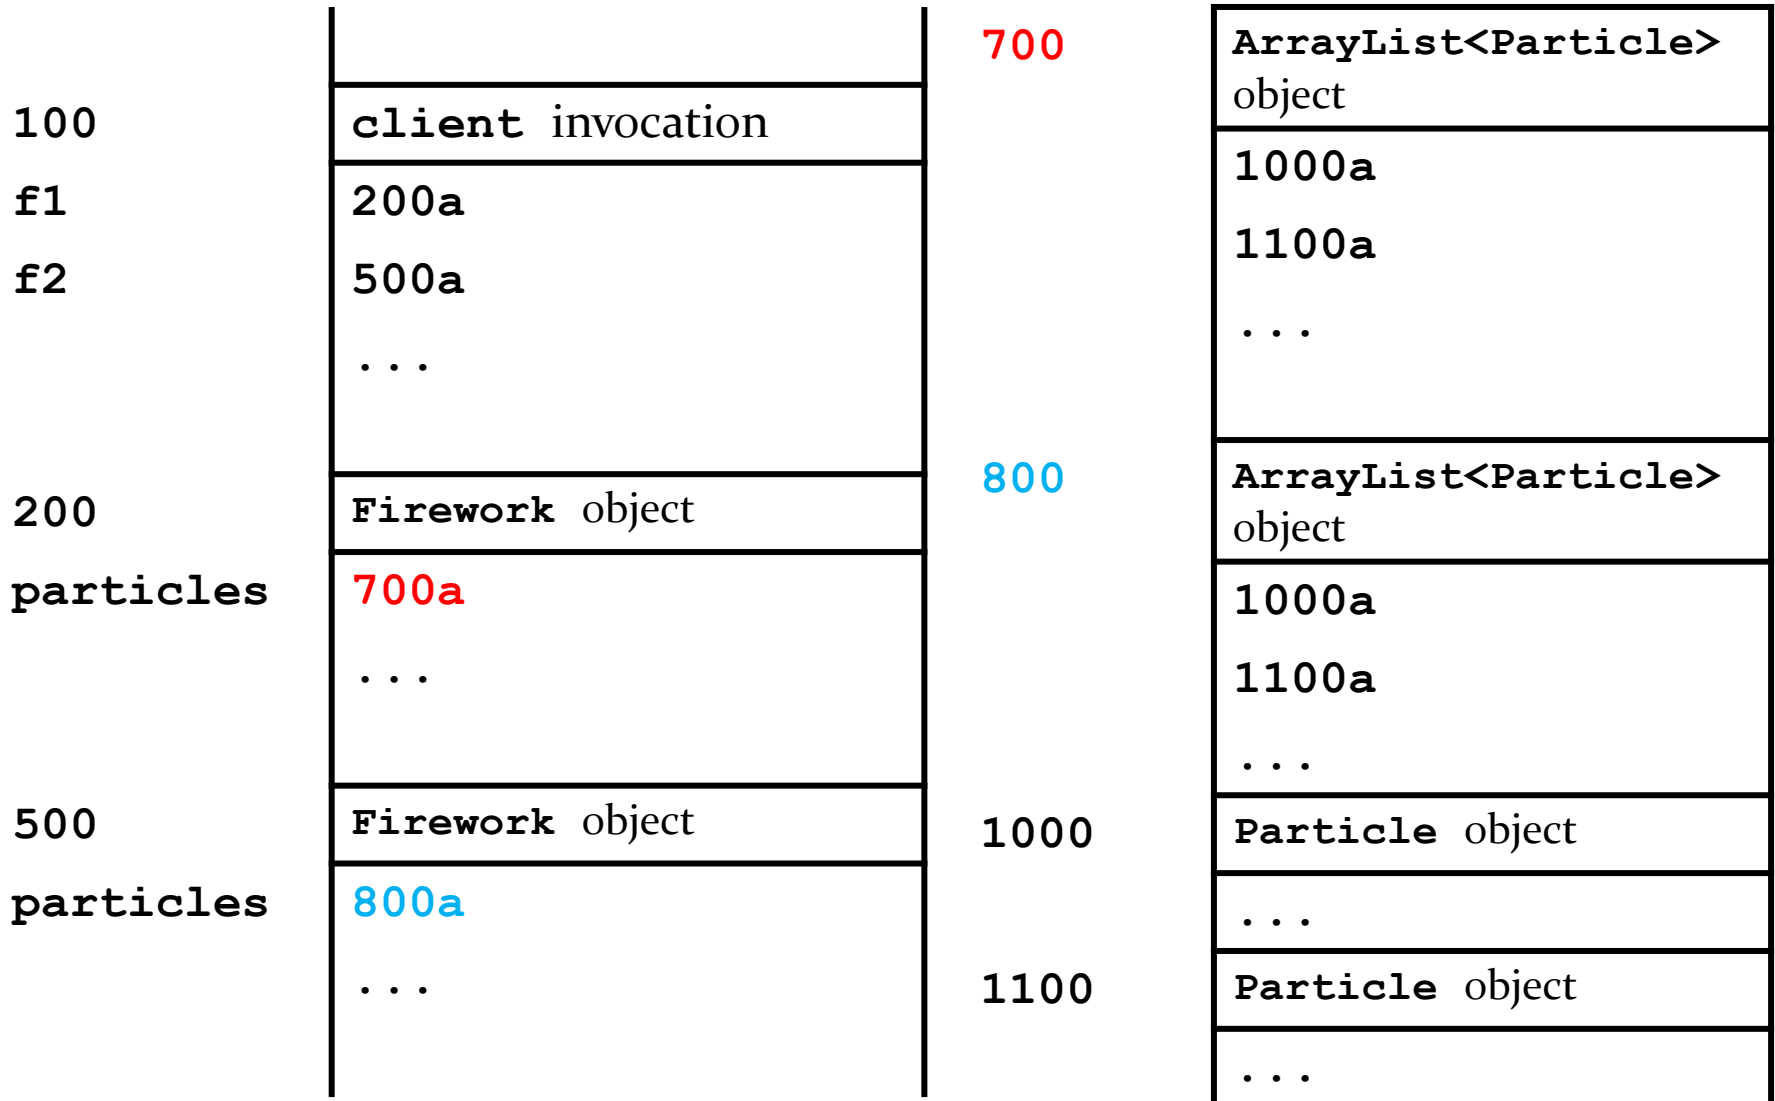

- ▶ the easy way to perform a shallow copy

```
// assume there is an ArrayList<Date> dates  
ArrayList<Date> sCopy = new ArrayList<Date>(dates);
```

```
/**
 * Initializes this firework so that its particles are a shallow copy
 * of the particles of another firework.
 *
 * @param other another firework
 */
public Firework(Firework other) {
    this.particles = new ArrayList<Particle>(other.particles);
}
```

shallow copy: new **List**
created, but no new
Particle objects created

```
Firework f2 = new Firework(f1);
```

► Worksheet Question 11

X Owns its Collection: Deep Copy

- ▶ if **X** owns its collection and the objects in the collection then the copy constructor must perform a deep copy of the collection
- ▶ a deep copy of a collection means
 - ▶ **X** creates a new collection
 - ▶ the references in the collection are references to new objects (that are copies of the objects in other collection)

X Owns its Collection: Deep Copy

- ▶ how to perform a deep copy

```
// assume there is an ArrayList<Date> dates
ArrayList<Date> dCopy = new ArrayList<Date>();
for(Date d : dates)
{
    dCopy.add(new Date(d.getTime()));
}
```

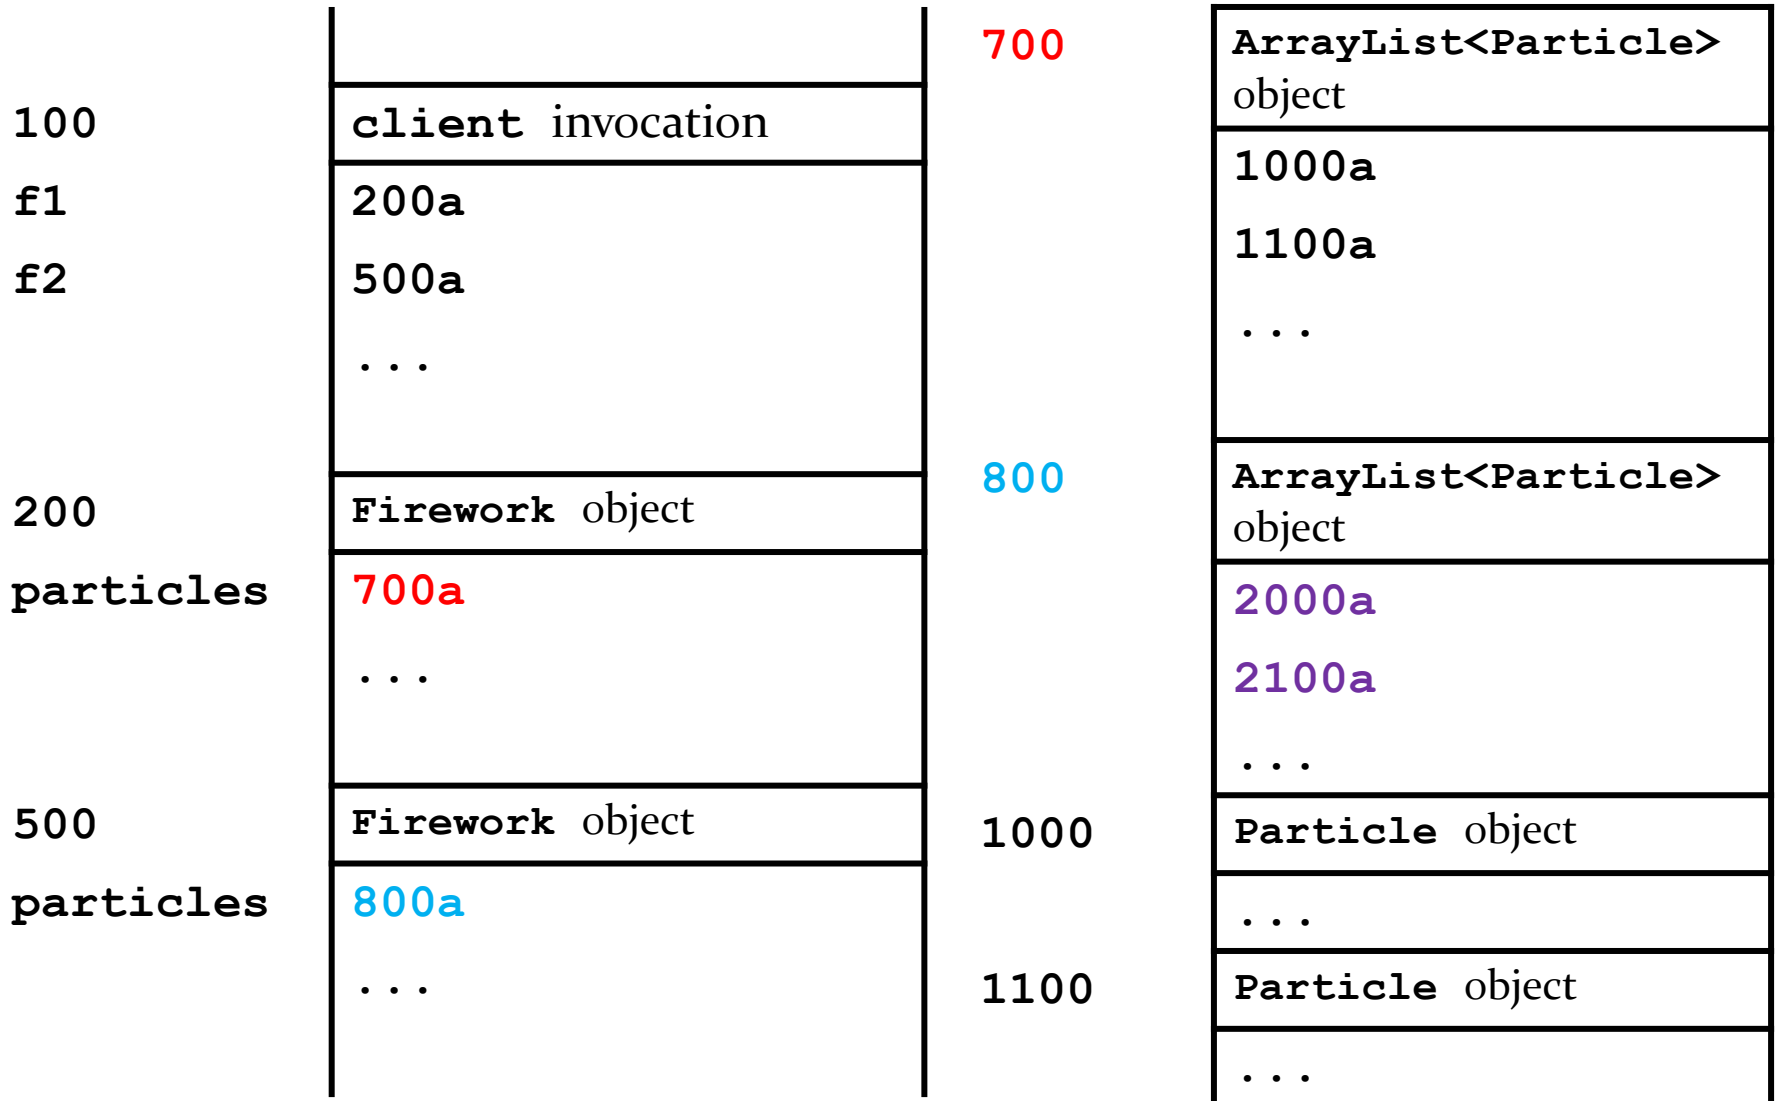

constructor invocation
creates a new object

deep copy: new **List**
created and new
elements created

```
/**
 * Initializes this firework so that its particles are a deep copy
 * of the particles of another firework.
 *
 * @param other another firework
 */
public Firework(Firework other) {
    this.particles = new ArrayList<Particle>();
    for (Particle p : other.particles) {
        this.particles.add(new Particle(p));
    }
}
```

deep copy: new **List**
created, and new
Particle objects created

```
Firework f2 = new Firework(f1);
```

2000

Particle object

...

2100

Particle object

...

► Worksheet Question 12
