A First Attempt: Good Design?

1111
-
LASSONDE
SCHOOL OF ENGINEERING

- Runtime execution ≈ a "bowl of spaghetti".
  - $\Rightarrow$  The system's behaviour is hard to predict, trace, and debug.
- Transitions hardwired as system's central control structure.
  - $\Rightarrow$  The system is vulnerable to changes/additions of states/transitions.
- All labelled blocks are largely similar in their code structures.
  - ⇒ This design "*smells*" due to duplicates/repetitions!
- The branching structure of the design exactly corresponds to that of the specific *transition graph*.

 $\Rightarrow$  The design is **application-specific** and **not reusable** for other interactive systems.

## A Top-Down, Hierarchical Solution

Separation of Concern Declare the transition table as a

feature the system, rather than its central control structure:

```
transition (src: INTEGER; choice: INTEGER): INTEGER
  -- Return state by taking transition 'choice' from 'src' state
 require valid_source_state: 1 \leq src \leq 6
         valid_choice: 1 \leq choice \leq 3
 ensure valid_target_state: 1 ≤ Result ≤ 6
```

• We may implement transition via a 2-D array.

						choice	
Сноісе		_	_		1	2	3
SRC STATE	1	2	3	1	6	5	2
1 (Initial)	6	5	2	2		1	3
2 (Flight Enquiry)	-	1	3	3		2	4
3 (Seat Enquiry)	-	2	4	state		-	
4 (Reservation)	_	3	5	4		3	5
5 (Confirmation)	-	4	1	5		4	1
6 (Final)	-	-	-	6			
				L			

7 of 29

## **Hierarchical Solution: Good Design?**

LASSONDE

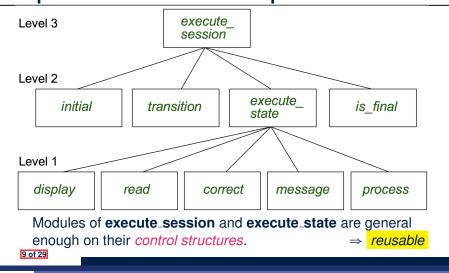

• This is a more general solution.

: State transitions are separated from the system's central control structure.

 $\Rightarrow$  **Reusable** for another interactive system by making changes only to the transition feature.

How does the central control structure look like in this design?

## Hierarchical Solution: Top-Down Functional Decomposition

## Hierarchical Solution: State Handling (1)

The following *control pattern* handles **all** states:

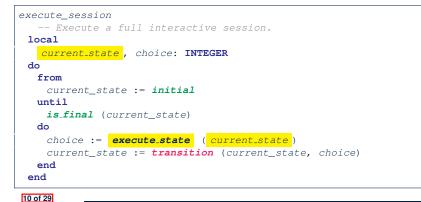

execute_state (	current_state : INTEGER) : INTEGER
Handle in	teraction at the current state.
Return us	er's exit choice.
local	
answer: ANSW	ER; valid_answer: BOOLEAN; choice: INTEGER
do	
from	
until	
valid_answe	er
do	
display( cu	rrent_state )
answer := 1	cead_answer( current_state )
choice := 1	cead_choice( current_state )
valid_answe	er := <b>correct</b> ( current_state , answer)
if not valu	d_answer <b>then message</b> ( current_state , answer)
end	
process(curr	rent_state , answer)
Result := ch	oice
end	
11 of 29	

## **Hierarchical Solution: System Control**

LASSONDE

LASSONDE

- All interactive sessions share the following control pattern:
- Start with some initial state.
- Repeatedly make *state transitions* (based on *choices* read from the user) until the state is *final* (i.e., the user wants to exit).

## Hierarchical Solution: State Handling (2)

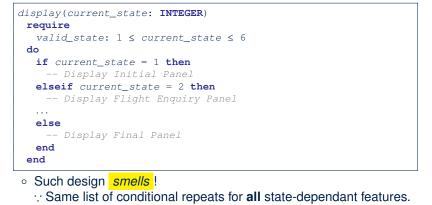

FEATURE CALL	Functionality
display( <mark>s</mark> )	Display screen outputs associated with state s
<pre>read_answer(\$)</pre>	Read user's input for answers associated with state s
<pre>read_choice(\$)</pre>	Read user's input for exit choice associated with state s
<i>correct</i> ( <i>s</i> , answer)	Is the user's answer valid w.r.t. state s?
process(s, answer)	Given that user's answer is valid w.r.t. state s,
	process it accordingly.
message(s, answer)	Given that user's answer is not valid w.r.t. state s,
	display an error message accordingly.

**Q**: How similar are the code structures of the above state-dependant commands or queries?

12 of 29

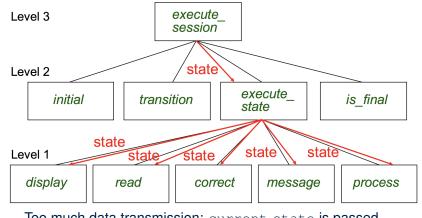

## Hierarchical Solution: State Handling (3)

**A**: Actions of all such state-dependant features must **explicitly** *discriminate* on the input state argument.

- Such design *violates* the *Single Choice Principle*.
- e.g., To add/delete a state  $\Rightarrow$  Add/delete a branch in all such features.

## **Hierarchical Solution: Pervasive States**

LASSONDE

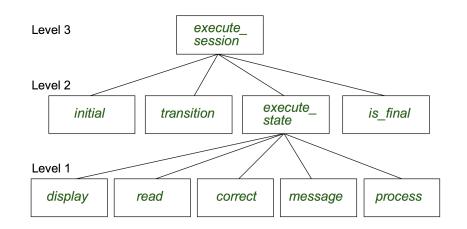

LASSONDE

Too much data transmission: current\_state is passed
From execute\_session (Level 3) to execute\_state (Level 2)
From execute\_state (Level 2) to all features at Level 1

15 of 29

LASSONDE

## Law of Inversion

#### If your routines exchange too many data, then put your routines in your data.

#### e.g.,

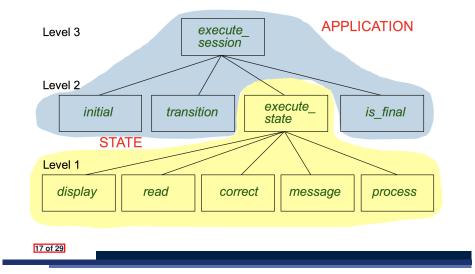

- execute\_state (Level 2) and all features at Level 1:
- Pass around (as *inputs*) the notion of *current\_state*
- Build upon (via *discriminations*) the notion of *current\_state*

<i>execute_state</i>	( <mark>s: INTEGER</mark>	)
display	( s: INTEGER	)
read_answer	( <mark>s: INTEGER</mark>	)
<i>read_choice</i>	( <mark>s: INTEGER</mark>	)
correct	( <mark>s: INTEGER</mark>	; answer: ANSWER)
process	( s: INTEGER	; answer: ANSWER)
message	( <mark>s: INTEGER</mark>	; answer: ANSWER)

- $\Rightarrow$  *Modularize* the notion of state as *class STATE*.
- $\Rightarrow$  **Encapsulate** state-related information via a **STATE** interface.
- ⇒ Notion of current\_state becomes implicit: the Current class.

LASSONDE

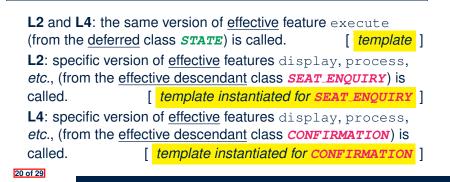

### The Template Design Pattern

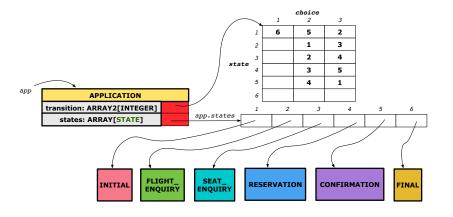

Consider the following fragment of Eiffel code:

- s: STATE create { SEAT\_ENOUIRY } s.make s.execute
- 3 4 create { CONFIRMATION } s.make
  - s.execute

## **APPLICATION Class: Array of STATE**

# LASSONDE

LASSONDE

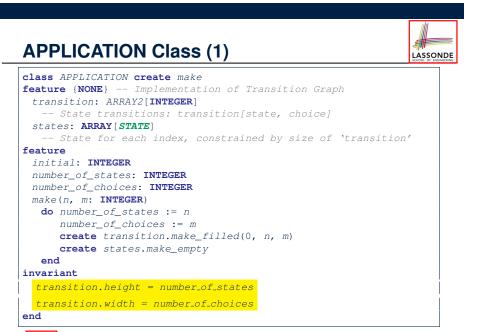

**APPLICATION Class (2)** 

23 of 29

LASSONDE

class APPLICATION feature {NONE} -- Implementation of Transition Graph transition: ARRAY2[INTEGER] states: ARRAY[STATE] feature put\_state(s: STATE; index: INTEGER) **require**  $1 \leq index \leq number of states$ do states.force(s, index) end choose initial(index: INTEGER) **require** 1 ≤ index ≤ number\_of\_states do initial := index end put\_transition(tar, src, choice: INTEGER) require  $1 \leq src \leq number_of_states$  $1 \leq tar \leq number of states$  $1 \leq choice \leq number_of_choices$ do transition.put(tar, src, choice) end end

21 of 29

## **Example Test: Non-Interactive Session**

```
test_application: BOOLEAN
 local
  app: APPLICATION ; current_state: STATE ; index: INTEGER
 do
  create app.make (6, 3)
  app.put_state (create {INITIAL}.make, 1)
  -- Similarly for other 5 states.
  app.choose_initial (1)
  -- Transit to FINAL given current state INITIAL and choice 1.
  app.put_transition (6, 1, 1)
   -- Similarly for other 10 transitions.
  index := app.initial
  current_state := app.states [index]
  Result := attached {INITIAL} current_state
  check Result end
  -- Say user's choice is 3: transit from INITIAL to FLIGHT_STATUS
  index := app.transition.item (index, 3)
  current_state := app.states [index]
  Result := attached {FLIGHT_ENQUIRY} current_state
end
24 of 29
```

22 of 29

## APPLICATION Class (3): Interactive Session

class A	APPLICATION
feature	e {NONE} Implementation of Transition Graph
trans	ition: ARRAY2[INTEGER]
state	S: ARRAY [STATE]
feature	3
execu	te_session
loca	31
си	rrent_state: <b>STATE</b>
in	dex: INTEGER
do	
fr	om
1	index := initial
un	til
L.	is_final (index)
10	op
	<pre>current_state := states[index] polymorphism</pre>
	current_state.execute dynamic binding
2	<pre>index := transition.item (index, current_state.choice)</pre>
en	d
end	
end

## Top-Down, Hierarchical vs. OO Solutions

LASSONDE

In the second (top-down, hierarchy) solution, it is required for every state-related feature to *explicitly* and *manually* discriminate on the argument value, via a a list of conditionals.
e.g., Given display(current\_state: INTEGER), the calls display(1) and display(2) behave differently.
The third (OO) solution, called the State Pattern, makes such conditional *implicit* and *automatic*, by making STATE as a deferred class (whose descendants represent all types of states), and by delegating such conditional actions to *dynamic binding*.
e.g., Given s: STATE, behaviour of the call s.display depends on the *dynamic type* of s (such as INITIAL vs. FLIGHT\_ENQUIRY).

Iding an Application
Create instances of STATE.
<pre>s1: STATE create {INITIAL} s1.make</pre>
Initialize an APPLICATION.
<pre>create app.make(number_of_states, number_of_choices)</pre>
Perform polymorphic assignments on app.states.
app.put_state(initial, 1)
Choose an initial state.
app.choose_initial(1)
Build the transition table.
app.put_transition(6, 1, 1)
Run the application.
app.execute_session 9
