Copying Objects Writing Complete Postconditions

EECS3311 A & E: Software Design Fall 2020

CHEN-WEI WANG

Upon completing this lecture, you are expected to understand:

- 3 Levels of *Copying Objects*: Reference vs. Shallow vs. Deep
- 2. Use of the old keyword in Postconditions
- **3.** Writing *Complete Postconditions* using logical quantifications: Universal (\forall) vs. Existential (\exists)

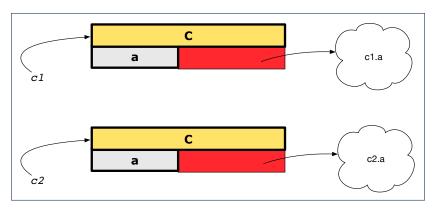

Copying Objects

Copying Objects

Say variables c1 and c2 are both declared of type C. [c1, c2: c]

- There is only one attribute a declared in class C.
- c1.a and c2.a are references to objects.

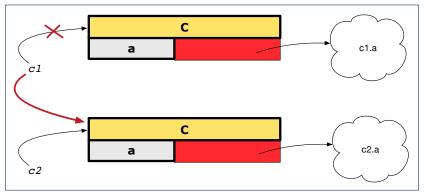

Copying Objects: Reference Copy

Reference Copy

c1 := c2

- Copy the address stored in variable c2 and store it in c1.
 - \Rightarrow Both c1 and c2 point to the same object.
 - ⇒ Updates performed via c1 also visible to c2.

[aliasing]

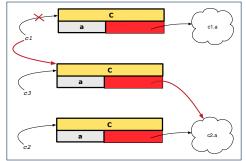

Shallow Copy

c1 := c2.twin

- Create a temporary, behind-the-scene object c3 of type C.
- Initialize each attribute a of c3 via reference copy: c3.a := c2.a
- Make a reference copy of c3:

c1 := c3

- \Rightarrow c1 and c2 *are not* pointing to the same object. [c1 /= c2]
- \Rightarrow c1.a and c2.a *are* pointing to the same object.
- \Rightarrow *Aliasing* still occurs: at 1st level (i.e., attributes of c1 and c2)

Deep Copy

c1 := c2.deep_twin

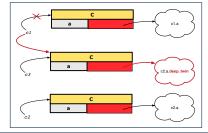

- Create a temporary, behind-the-scene object c3 of type C.
- Recursively initialize each attribute a of c3 as follows:

```
Base Case: a is primitive (e.g., INTEGER). \Rightarrow c3.a := c2.a. Recursive Case: a is referenced. \Rightarrow c3.a := c2.a. deep_twin
```

Make a reference copy of c3:

c1 := c3

- \Rightarrow c1 and c2 *are not* pointing to the same object.
- \Rightarrow c1.a and c2.a are not pointing to the same object.
- ⇒ No aliasing occurs at any levels.

Copying Objects

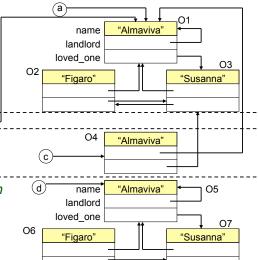

• Initial situation:

■ Result of:

b := a (b)

c := a.twin

d := a.deep_twin

Example: Collection Objects (1)

 In any OOPL, when a variable is declared of a type that corresponds to a known class (e.g., STRING, ARRAY, LINKED_LIST, etc.):

At *runtime*, that variable stores the *address* of an object of that type (as opposed to storing the object in its entirety).

Assume the following variables of the same type:

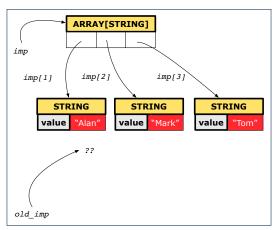

```
local
  imp : ARRAY[STRING]
  old_imp: ARRAY[STRING]
do
  create {ARRAY[STRING]} imp.make_empty
  imp.force("Alan", 1)
  imp.force("Mark", 2)
  imp.force("Tom", 3)
```

- Before we undergo a change on imp, we "copy" it to old_imp.
- After the change is completed, we compare imp vs. old_imp.
- Can a change always be visible between "old" and "new" imp?

Example: Collection Objects (2)

- Variables imp and old_imp store address(es) of some array(s).
- Each "slot" of these arrays stores a STRING object's address.

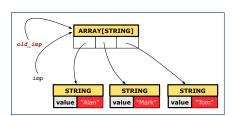

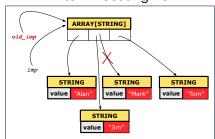

Reference Copy of Collection Object

```
cold.imp := imp
Result := old_imp = imp -- Result = true
imp[2] := "Jim"
Result :=
    across 1 | . . | imp.count is j
    all imp [j] ~ old_imp [j]
    end -- Result = true
```

Before Executing L3

After Executing L3

11 of 41

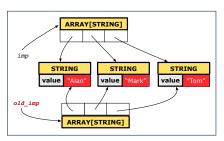

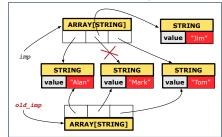

```
cold.imp := imp.twin
Result := old_imp = imp -- Result = false
imp[2] := "Jim"
Result :=
    across 1 | . . | imp.count is j
    all imp [j] ~ old_imp [j]
    end -- Result = false
```

Before Executing L3

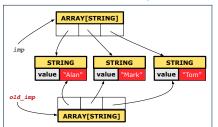

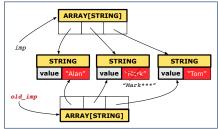

```
old.imp := imp.twin
Result := old_imp = imp -- Result = false
imp[2].append ("***")
Result :=
   across 1 | . . | imp.count is j
   all imp [j] ~ old_imp [j]
   end -- Result = true
```

Before Executing L3

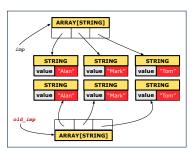

Deep Copy of Collection Object (1)

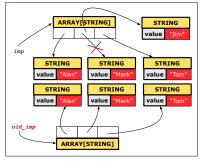

```
old_imp := imp.deep_twin

Result := old_imp = imp -- Result = false
imp[2] := "Jim"

Result :=
   across 1 | . . | imp.count is j
   all imp [j] ~ old_imp [j] end -- Result = false
```

Before Executing L3

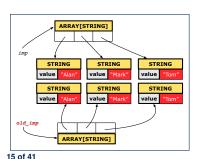

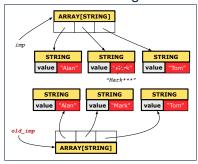

Deep Copy of Collection Object (2)

```
cld_imp := imp.deep_twin
Result := old_imp = imp -- Result = false
imp[2].append ("***")
Result :=
   across 1 | . . | imp.count is j
   all imp [j] ~ old_imp [j] end -- Result = false
```

Before Executing L3

Experiment: Copying Objects

• **Download** the Eiffel project archive (a zip file) here:

```
https://www.eecs.yorku.ca/~jackie/teaching/lectures/2020/F/
EECS3311/codes/copying_objects.zip
```

- Unzip and compile the project in Eiffel Studio.
- Reproduce the illustrations explained in lectures.

Writing Complete Postconditions

How are contracts checked at runtime?

- All contracts are specified as Boolean expressions.
- Right <u>before</u> a feature call (e.g., acc.withdraw(10)):
 - The current state of acc is called its *pre-state*.
 - Evaluate pre-condition using current values of attributes/queries.
 - Cache values, via := , of old expressions in the post-condition.

```
old accounts[i].id
                                                                       [ old_accounts_i_id := accounts[i].id ]
e.g.,
      (old accounts[i]).id
                                                                            [ old_accounts_i := accounts[i] ]
e.g.,
      (old accounts[i].twin).id
e.a..
                                                                   old_accounts_i_twin := accounts[i].twin ]
      (old accounts)[i].id
                                                                               [ old_accounts := accounts ]
e.g.,
      (old accounts.twin)[i].id
                                                                     [ old_accounts_twin := accounts.twin ]
e.g.,
      (old Current).accounts[i].id
                                                                                  [ old_current := Current ]
      (old Current.twin).accounts[i].id
                                                                        [ old_current_twin := Current.twin ]
```

- Right after the feature call:
 - The current state of acc is called its post-state.
 - Evaluate post-condition using both current values and "cached" values of attributes and queries.

18 of 41 • Evaluate invariant using current values of attributes and queries.

When are contracts complete?

- In *post-condition*, for *each attribute*, specify the relationship between its *pre-state* value and its *post-state* value.
 - o Eiffel supports this purpose using the old keyword.
- This is tricky for attributes whose structures are composite rather than simple:
 - e.g., ARRAY, LINKED_LIST are composite-structured.
 - e.g., INTEGER, BOOLEAN are simple-structured.
- **Rule of thumb:** For an attribute whose structure is composite, we should specify that after the update:
 - 1. The intended change is present; and
 - 2. The rest of the structure is unchanged.
- The second contract is much harder to specify:
 - Reference aliasing [ref copy vs. shallow copy vs. deep copy]
 - Iterable structure

Account

```
class
 ACCOUNT
inherit
 ANY
   redefine is_equal end
create
 make
feature -- Attributes
 owner: STRING
 balance: INTEGER
feature -- Commands
 make (n: STRING)
   do
   owner := n
    balance := 0
   end
```

```
deposit(a: INTEGER)
  do
    balance := balance + a
   ensure
    balance = old balance + a
   end
 is_equal(other: ACCOUNT): BOOLEAN
  do
    Result :=
          owner ~ other.owner
      and balance = other.balance
  end
end
```

Bank

```
class BANK
create make
feature
 accounts: ARRAY [ACCOUNT]
 make do create accounts.make_empty end
 account of (n: STRING): ACCOUNT
   require -- the input name exists
    existing: across accounts is acc some acc.owner ~ n end
      -- not (across accounts is acc all accowner /~ n end)
  do ... ensure Result. owner ~ n end
 add (n: STRING)
   require -- the input name does not exist
    non_existing: across accounts is acc all acc.owner /~ n end
      -- not (across accounts is acc some acc.owner ~ n end)
   local new account: ACCOUNT
  do
    create new account.make (n)
    accounts.force (new account, accounts.upper + 1)
  end
end
```

We examine 5 different versions of a command

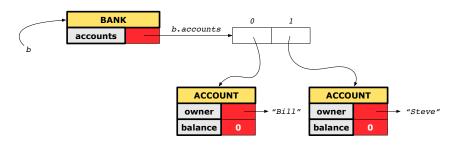

deposit_on (n: STRING; a: INTEGER)

VE	RSION	IMPLEMENTATION	CONTRACTS	SATISFACTORY?
	1	Correct	Incomplete	No
	2	Wrong	Incomplete	No
	3	Wrong	Complete (reference copy)	No
	4	Wrong	Complete (shallow copy)	No
	5	Wrong	Complete (deep copy)	Yes

We will test each version by starting with the same runtime object structure:

Version 1: Lass Incomplete Contracts, Correct Implementation

```
class BANK
 deposit on v1 (n: STRING; a: INTEGER)
   require across accounts is acc some acc.owner ~ n end
   local i: INTEGER
   do
    from i := accounts.lower
    until i > accounts.upper
    1000
      if accounts[i].owner ~ n then accounts[i].deposit(a) end
     i := i + 1
    end
   ensure
    num_of_accounts_unchanged:
      accounts.count = old accounts.count
    balance of n increased:
      Current.account_of(n).balance =
       old Current.account_of(n).balance + a
   end
end
```

```
class TEST_BANK
 test_bank_deposit_correct_imp_incomplete_contract: BOOLEAN
   local
    b: BANK
   do
    comment("t1: correct imp and incomplete contract")
    create b.make
    b.add ("Bill")
    b.add ("Steve")
    -- deposit 100 dollars to Steve's account
    b.deposit_on_v1 ("Steve", 100)
    Result :=
         b.account_of("Bill").balance = 0
      and b.account of ("Steve").balance = 100
    check Result end
 end
end
```

APPLICATION

Note: * indicates a violation test case

PASSED (1 out of 1)			
Case Type	Passed	Total	
Violation	0	0	
Boolean	1	1	
All Cases	1	1	
State	Contract Violation	Test Name	
Test1	TEST_BANK		
PASSED	NONE	t1: test deposit_on with correct imp and incomplete contract	

Version 2: Incomplete Contracts, Wrong Implementation

```
class BANK
 deposit on v2 (n: STRING; a: INTEGER)
   require across accounts is acc some acc.owner ~ n end
   local i: INTEGER
  do ...
    -- imp. of version 1, followed by a deposit into 1st account
    accounts[accounts.lower].deposit(a)
   ensure
    num of accounts unchanged:
      accounts.count = old accounts.count
    balance_of_n_increased:
     Current.account_of(n).balance =
       old Current.account_of(n).balance + a
   end
end
```

Current postconditions lack a check that accounts other than ${\bf n}$ are unchanged.

```
class TEST_BANK
test_bank_deposit_wrong_imp_incomplete_contract: BOOLEAN
 local
  h: BANK
 do
   comment("t2: wrong imp and incomplete contract")
   create b.make
  b.add ("Bill")
  b.add ("Steve")
   -- deposit 100 dollars to Steve's account
   b.deposit_on_v2 ("Steve", 100)
   Result :=
       b.account of ("Bill").balance = 0
    and b.account of ("Steve").balance = 100
   check Result end
 end
end
```

Experiment: Complete Postconditions

• **Download** the Eiffel project archive (a zip file) here:

```
https://www.eecs.yorku.ca/~jackie/teaching/lectures/2020/F/
EECS3311/codes/array_math_contract.zip
```

- Unzip and compile the project in Eiffel Studio.
- Reproduce the illustrations explained in lectures.

Beyond this lecture

- Consider the query account_of (n: STRING) of BANK.
- How do we specify (part of) its postcondition to assert that the state of the bank remains unchanged:

```
o accounts = old accounts
o accounts = old accounts.twin
o accounts = old accounts.deep.twin
o accounts ~ old accounts
o accounts ~ old accounts.twin
o accounts ~ old accounts.twin
o accounts ~ old accounts.deep.twin
[v]
```

- Which equality of the above is appropriate for the postcondition?
- Why is each one of the other equalities not appropriate?
